CELTÆ, or CELTES, an ancient nation, by which most of the countries of Europe are thought to have been peopled. The compilers of the Universal History are of opinion, that they are descended from Gomer the eldest son of Japhet, the son of Noah. They think that Gomer settled in the province of Phrygia in Asia: Ashkenaz his eldest son, or Togarmah his youngest, or both, in Armenia, and Riphath the second son in Cappadocia. When they spread themselves wider, they seem to have moved regularly in columns without interfering with or disturbing their neighbours. The descendants of Gomer, or the Celtæ, took the left hand, insensibly spreading themselves westward towards Poland, Hungary, Germany, France, and Spain; while the descendants of Magog, Gomer's brother, moving eastward, peopled Tartary.

In this large European tract, the Celtes began to appear a powerful nation under a regular monarchy, or rather under several considerable kingdoms. Mention is made of them indeed in so many parts of Europe, by ancient geographers and historians, that Ortelius took *Celtica* to be a general name for the continent of Europe, and made a map of it bearing this title. In those parts of Asia, which they possessed, as well as in the different parts of Europe, the Celtes went by various names. In Lesser Asia they were known by the names of *Titans* and *Sacks*; in the northern parts of Europe, by those of *Cymmerians*, *Cymbrians*, &c.; and in the southern parts they were called *Celtes*, *Gauls*, or *Galatians*.

With respect to the government of the Celtes we are entirely in the dark. All we know is, that the curetes, and afterwards druids and bards, were the interpreters of their laws; judged all causes whether criminal or civil; and their sentence was reckoned so sacred, that whoever refused to abide by it was by them excluded from assisting at their sacred rites; after which no man dared converse with him; so that this punishment was reckoned the most severe of all, even severer than death itself.

They neither reared temples nor statues to the deity, but destroyed them wherever they could find them, planting in their stead large spacious groves; which being open on the top and sides, were, in their opinion, more acceptable to the divine Being, who is absolutely unconfined. In this their religion seems to have resembled that of the Perses and disciples of Zoroaster. The Celtes only differed from them in making the oak instead of the fire the emblem of the deity; in choosing that tree above all others to plant their groves with, and attributing several supernatural virtues both to its wood, leaves, fruit, and misletoe; all which were made use of in their sacrifices and

other parts of their worship. But after they had adopted the idolatrous superstition of the Romans and other nations, and the apotheosis of their heroes and princes, they came to worship them much in the same manner: as Jupiter under the name of *Taran*, which in the Celtic signifies thunder: Mercury, whom some authors call *Heus* or *Hesus*, probably, from the Celtic *huadh*, which signifies a dog, and might be the *Anubis latrans* of the Egyptians. But Mars was held in the greatest veneration by the warlike, and Mercury by the trading part of the nation. The care of religion was immediately under their curetes, since known by the name of druids and bards. These were, as Cæsar tells us, the performers of sacrifices and all religious rites, and expounders of religion to the people. They also instructed youth in all kinds of learning, such as philosophy, astronomy, astrology, &c. Their doctrines were taught only by word of mouth, esteeming them too sacred to be committed to writing. Other more common subjects, such as their hymns to their gods, the exploits of princes and generals in time of war, and especially before a battle, were couched in elegant verse, and recited, or rather sung, on all proper occasions; though even these were also kept from vulgar eyes, and either committed to memory, or if to writing, the whole was a secret to all the laity. The latter indeed seems the most probable, if what Cæsar hints be true; namely, that these poetic records were increased in his time to such a bulk, that it took up a young bard near 20 years to learn them by heart. Diodorus tells us farther, that these poets used to accompany their songs with instrumental music, such as that of organs, harps, and the like; and that they were held in such veneration, that if, in the time of an engagement between two armies, one of these bards appeared, both sides immediately ceased fighting. The reason of this was, that they were universally believed to be prophets as well as poets; so that it was thought dangerous as well as injurious to disobey what they supposed came from their gods. These prophetic philosophers kept academies, which were resorted to not only by a great number of their own youth, but also of those from other countries, insomuch that Aristotle says, their philosophy passed from thence into Greece, and not from Greece thither. Diodorus likewise quotes a passage from Hecateus, which is greatly in their praise; viz. that the druids had some kind of instruments by which they could draw distant objects nearer, and make them appear larger and plainer; and by which they could discover even seas, mountains, and valleys, in the moon. But whatever might be their learning, it is certain, that in process of time they adopted several very barbarous customs, such as sacrificing human victims to their gods as more acceptable to them than those of any other animals. And Diodorus tells us of another inhuman custom they used in their divinations, especially in great matters, which was done by killing some of their slaves, or some prisoners of war, if any they had, with a scimitar, to draw their augury from the running of his blood from his mangled limbs.

For the history, &c. of the different Celtic nations see the article GAUL, &c.

CELTES, certain ancient instruments of a wedge-like form, of which several have been discovered in
N n 2 different

Celtæ,

Celtiberia,
Celtis.

different parts of Great Britain. Antiquarians have generally attributed them to the Celtæ; but, not agreeing as to their use, distinguished them by the above unmeaning appellation. But Mr Whittaker makes it probable that they were British battle-axes. See *BATTLE-AX*.

CELTIBERIA (anc. geog.), a county of the Hither Spain, along the right or south-west side of the river Iberus; though sometimes the greatest part of Spain was called by the name of *Celtiberia*. The people were denominated *Celtiberi*, or the Celtæ seated on the Iberus. They were very brave and warlike, their cavalry in particular was excellent. They wore a black and rough cloak, the shag of which was like goats hair. Some of them had light bucklers like the Gauls; other hollow and round ones like those of other nations. They all wore boots made of hair, and iron helmets adorned with crests of a purple colour. They used swords which cut on both sides, and poinards of a foot long. Their arms were of an admirable temper, and are said to have been prepared in the following manner: they buried plates of iron under ground, where they let them remain till the rust had eaten the weakest part of the metal, and the rest was consequently hard and firm. Of this excellent iron they made their swords, which were so strong and well tempered, that there was neither buckler nor helmet that could resist their edge. The Celtiberians were very cruel towards their enemies and malefactors, but showed the greatest humanity to their guests. They not only cheerfully granted their hospitality to strangers who travelled in their country, but were desirous that they should seek protection under their roof.

CELTIS, in botany: A genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 53d order, *Scabridæ*. It is an hermaphrodite plant: The female calyx is quinquepartite; there is no corolla; there are five stamens, and two styles. The fruit is a monospermous plum. In the male, there is no calyx: the corolla is hexapetalous; there are six stamens, and an embryo of a pistillum. There are three species, all of them deciduous, viz.

1. The *Australis* or Southern Celtis, a deciduous tree, native of Africa and the South of Europe. 2. The *Occidentalis* or Western Celtis, a native of Virginia. And 3. The *Orientalis* or Eastern Celtis, a native of Armenia. The two first species grow with large, fair, straight stems; their branches are numerous and diffuse; their bark is of a darkish grey colour; their leaves are of a pleasant green; three or four inches long, deeply ferrated, end in a narrow point, nearly resemble the leaves of the common stinging-nettle, and continue on the trees till late in the autumn: So that one may easily conceive what an agreeable variety these trees would make. Add to this, their shade is admirable. The leaves are late in the spring before they show themselves; but they make amends for this, by retaining their verdure till near the close of autumn, and then do not resemble most deciduous trees, whose leaves show their approaching fall by the change of their colour; but continue to exhibit themselves of a pleasant green even to the last. Hanbury speaks highly of the celtis as a timber-tree: he says, "The wood

of the Lote-tree is extremely durable. In Italy they make their flutes, pipes, and other wind-instruments of it. With us the coach-makers use it for the frames of their vehicles." Millar mentions also the wood of the *Occidentalis* being used by the coach-makers. The third species will grow to about twelve feet; and the branches are numerous, smooth, and of a greenish colour. The leaves are smaller than those of the other sorts, though they are of a thicker texture, and of a lighter green. The flowers come out from the wings of the leaves, on slender footstalks: They are yellowish, appear early in the spring, and are succeeded by large yellow fruit.

Propagation, &c. All the species are propagated from seeds, which ripen in England, if they have a favourable autumn; but the foreign seeds are the most certain of producing a crop. These seeds should be sown, soon after they are ripe, either in boxes, or in a fine warm border of rich earth, a quarter of an inch deep; and in the following spring many of the young plants will appear; though a great part often lie till the second spring before they show their heads. If the seeds in the beds shoot early in the spring, they should be hooped, and protected by mats from the frosts, which would nip them in the bud. When all danger from frosts is over, the mats should be laid aside till the parching beams of the sun get powerful; when, in the day-time, they may be laid over the hoops again, to screen the plants from injury. The mats should be constantly taken off every night, and the young plants should never be covered either in rainy or cloudy weather. During the whole summer, these seedlings should be frequently watered in dry weather, and the beds kept clean of weeds, &c. In the autumn, they must be protected from the frosts, which often come early in that season, and would not fail to destroy their tops. The like care should be continued all winter to defend them from the same enemies. In this seminary they may remain, being kept clean of weeds and watered in dry weather, till the end of June, when they should be taken out of their beds, and planted in others at six inches distance. And here let no one (continues Hanbury) be startled at my recommending the month of June for this work; for I have found by repeated experience, that the plants will be then almost certain of growing, and will continue their shoots till the autumn; whereas I have ever perceived, that many of those planted in March have frequently perished, and that those which did grow made hardly any shoot that year, and showed the early figure of a stunted tree. In June, therefore, let the ground be well dug, and prepared for this work; and let the mould be rich and good: But the operation of removing must be deferred till rain comes; and if the season should be dry, this work may be postponed till the middle of July. After a shower, therefore, or a night's rain, let the plants be taken out of their beds, and pricked out at six inches distance from each other. After this, the beds in which they are planted should be hooped, and covered with mats when the sun shines; but these must always be taken away at night, as well as in rainy or cloudy weather. With this management, they will have shot to a good height by the autumn, and have acquired so much hardiness and strength as to need no farther care than to be kept clear

Celtis.

Cement. clear of weeds for two or three years; when they may be planted out in places where they are to remain, or set in the nursery, to be trained up for large standards. The best season for planting out these standard trees is the latter end of October, or beginning of November; and in performing that operation, the usual rules must be observed with care. The soil for the lute-tree should be light, and in good heart; and the situation ought to be well defended, the young shoots being very liable to be destroyed by the winter's frosts.

CEMENT, in a general sense, any glutinous substance capable of uniting and keeping things together in close cohesion. In this sense the word *cement* comprehends mortar, folder, glue, &c. but has been generally restrained to the compositions used for holding together broken glasses, china, and earthen ware. For this purpose the juice of garlic is recommended as exceedingly proper, being both very strong, and, if the operation is performed with care, leaving little or no mark. Quicklime and the white of an egg mixed together, and expeditiously used, are also very proper for this purpose. Dr Lewis recommends a mixture of quicklime and cheese, in the following manner: "Sweet cheese shaved thin and stirred with boiling hot water, changes into a tenacious slime which does not mingle with the water. Worked with fresh parcels of hot water, and then mixed upon a hot stone with a proper quantity of unslaked lime, into the consistence of a paste, it proves a strong and durable cement for wood, stone, earthen-ware, and glass. When thoroughly dry, which will be in two or three days, it is not in the least acted upon by water. Cheese barely beat with quicklime, as directed by some of the chemists for luting cracked glasses, is not near so efficacious." A composition of the drying oil of linseed and white-lead is also used for the same purposes, but is greatly inferior.

CEMENT in building, is used to denote any kind of mortar of a stronger kind than ordinary. The cement commonly used is of two kinds; hot, and cold. The hot cement is made of rosin, bees wax, brick-dust, and chalk, boiled together. The bricks to be cemented are heated, and rubbed one upon another, with cement between them. The cold cement is that above described for cementing china, &c. which is sometimes, though rarely, employed in building.

The ruins of the ancient Roman buildings are found to cohere so strongly, that most people have imagined the ancients were acquainted with some kind of mortar, which, in comparison of ours, might justly be called *cement*; and that to our want of knowledge of the materials they used, is owing the great inferiority of modern buildings in their durability. In 1770, one M. Lorient, a Frenchman, pretended to have discovered the secret of the ancient cement, which, according to him, was no more than a mixture of powdered quicklime with lime which had been long slaked and kept under water. The slaked lime was first to be made up with sand, earth, brick-dust, &c. into mortar after the common method, and then about a third part of quicklime in powder was added to the mixture. This produced an almost instantaneous petrification, something like what is called the *setting* of alabaster, but in a much stronger degree; and was possessed of many wonderful qualities needless here to relate, seeing it has never

been known to succeed with any other person who tried it. Mr Anderson, in his essays on agriculture, has discussed this subject at considerable length, and seemingly with great judgment. He is the only person we know, who has given any rational theory of the uses of lime in building, and why it comes to be the proper basis of all cements. His account is in substance as follows:

Lime which has been slaked and mixed with sand, becomes hard and consistent when dry, by a process similar to that which produces the natural *stalactites* in caverns. These are always formed by water dropping from the roof. By some unknown and inexplicable process of nature, this water has dissolved in it a small portion of calcareous matter in a *caustic* state. As long as the water continues covered from the air, it keeps the earth dissolved in it; it being the natural property of calcareous earths, when deprived of their fixed air, to dissolve in water. But when the small drop of water comes to be exposed to the air, the calcareous matter contained in it begins to attract the fixable part of the atmosphere. In proportion as it does so, it also begins to separate from the water, and to reassume its native form of limestone or marble. This process Mr Anderson calls a *crystallization*; and when the calcareous matter is perfectly *crystallized* in this manner, he affirms that it is to all intents and purposes limestone or marble of the same consistence as before: and "in this manner (says he), within the memory of man, have huge rocks of marble been formed near Matlock in Derbyshire." If lime in a caustic state is mixed with water, part of the lime will be dissolved, and will also begin to crystallize. The water which parted with the crystallized lime, will then begin to act upon the remainder, which it could not dissolve before; and thus the process will continue, either till the lime be all reduced to an *effete*, or (as he calls it) *crystalline* state, or something hinders the action of the water upon it. It is this crystallization which is observed by the workmen when a heap of lime is mixed with water, and left for some time to macerate. A hard crust is formed upon the surface, which is ignorantly called *frosting*, though it takes place in summer as well as in winter. If therefore the hardness of the lime, or its becoming a cement, depends entirely on the formation of its crystals, it is evident, that the perfection of the cement must depend on the perfection of the crystals, and the hardness of the matters which are entangled among them. The additional substances used in making of mortar, such as sand, brick-dust, or the like, according to Mr Anderson, serve only for a purpose similar to what is answered by sticks put into a vessel full of any saline solution, namely, to afford the crystals an opportunity of fastening themselves upon it. If therefore the matter interposed between the crystals of the lime is of a friable, brittle nature, such as brick dust or chalk, the mortar will be of a weak and imperfect kind; but when the particles are hard, angular, and very difficult to be broken, such as those of river or pit-sand, the mortar turns out exceedingly good and strong. Sea-sand is found to be an improper material for mortar, which Mr Anderson ascribes to its being less angular than the other kinds. That the crystallization may be the more perfect, he also recommends a large quantity of water, that the ingredients

Cement.

Cement. be perfectly mixed together, and that the drying be as slow as possible. An attention to these circumstances, he thinks, would make the buildings of the moderns equally durable with those of the ancients; and from what remains of the ancient Roman works, he thinks a very strong proof of his hypothesis might be adduced. The great thickness of their walls necessarily required a vast length of time to dry. The middle of them was composed of pebbles thrown in at random, and which have evidently had mortar so thin as to be *poured* in among them. By this means, a great quantity of the lime would be dissolved, and the crystallization performed in the most perfect manner; and the indefatigable pains and perseverance for which the Romans were so remarkable in all their undertakings, leave no room to doubt that they would take care to have the ingredients mixed together as well as possible. The consequence of all this is, that the buildings formed in this manner are all as firm as if cut out of a solid rock; the mortar being equally hard, if not more so, than the stones themselves.

Notwithstanding the bad success of those who have attempted to repeat M. Lorient's experiments, however, Dr Black informs us, that a cement of this kind is certainly practicable. It is done, he says, by powdering the lime while hot from the kiln, and throwing it into a thin paste of sand and water; which, not flaking immediately, absorbs the water from the mortar by degrees, and forms a very hard mass. "It is plain (he adds) that the strength of this mortar depends on using the lime hot or fresh from the kiln."

By mixing together gypsum and quick-lime, and then adding water, we may form a cement of tolerable hardness, and which apparently might be used to advantage in making troughs for holding water, or lining small canals for it to run in. Mr Wiegand says, that a good mortar or cement, which will not crack, may be obtained by mixing three parts of a thin magma of slaked lime with one of powdered gypsum; but adds, that it is used only in a dry situation. A mixture of tarra with slaked lime acquires in time a stoney hardness, and may be used for preventing water from entering. See MORTAR and STUCCO.

• See the foregoing article.

CEMENT, among engravers, jewellers, &c. is the same with the hot cement used in building*; and is used for keeping the metals to be engraven firm to the block, and also for filling up what is to be chiseled.

CEMENT, in chemistry, is used to signify all those powders and pastes with which any body is surrounded in pots or crucibles, and which are capable by the help of fire of producing changes upon that body. They are made of various materials; and are used for different purposes, as for parting gold from silver, converting iron into steel, copper into brass: and by cementation more considerable changes can be effected upon bodies, than by applying to them liquids of any kind; because the active matters are then in a state of vapour, and assisted by a very considerable degree of heat.

CEMENT which quickly hardens in Water. This is described in the posthumous works of Mr Hooke, and is recommended for gilding live craw-fish, carps, &c. without injuring the fish. The cement for this purpose is prepared, by putting some Burgundy pitch into a new earthen pot, and warming the vessel till it re-

ceives so much of the pitch as will stick round it; then strewing some finely powdered amber over the pitch when growing cold, adding a mixture of three pounds of linseed oil, and one of oil of turpentine, covering the vessel and boiling them for an hour over a gentle fire, and grinding the mixture as it is wanted with as much pumice-stone in fine powder as will reduce it to the consistence of paint. The fish being wiped dry, the mixture is spread upon it; and the gold leaf being then laid on, the fish may be immediately put into water again, without any danger of the gold coming off, for the matter quickly grows hard in the water.

CEMENT-Pots, are those earthen pots used in the cementation of metals.

CEMENTATION, the act of corroding or otherwise changing a metal by means of a CEMENT.

CEMETERY (*κοιμητήριον*, from *κοιμάω* to "sleep;") a place set apart or consecrated for the burial of the dead.

Anciently none were buried in churches or churchyards: it was even unlawful to inter in cities, and the cemeteries were without the walls. Among the primitive Christians these were held in great veneration. It even appears from Eusebius and Tertullian, that, in the early ages, they assembled for divine worship in the cemeteries. Valerian seems to have confiscated the cemeteries and other places of divine worship, but they were restored again by Gallienus. As the martyrs were buried in these places, the Christians chose them for building churches on, when Constantine established their religion; and hence some derive the rule which still obtains in the church of Rome, never to consecrate an altar without putting under it the relics of some saint. The practice of consecrating cemeteries is of some antiquity. The bishop walked round it in procession, with the crozier or pastoral staff in his hand, the holy water-pot being carried before, out of which the aspersions were made.

CENCHRUS, in botany: A genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 4th order, *Gramina*. The involucre is lacinated, and echinated, or beset with small prickles, and biflorous. The calyx is a biflorous glume, with one floret-male, and the other hermaphrodite. The hermaphrodite corolla is a pointless glume; there are three stamina; one seed; the male corolla a pointless glume; with three stamina.

CENEGILD, in the Saxon Antiquities, an expiatory mulct, paid by one who had killed a man, to the kindred of the deceased. The word is compounded of the Saxon *cinne*, i. e. *cognatio*, "relation", and *gild*, *solutio*, "payment".

CENOBITE. See COENOBITE.

CENOTAPH, in antiquity, an empty tomb, erected by way of honour to the deceased. It is distinguished from a sepulchre, in which a coffin was deposited. Of these there were two sorts; one for those who had, and another for those who had not, been honoured with funeral rites in another place.

The sign whereby honorary sepulchres were distinguished from others, was commonly the wreck of a ship, to denote the decease of the person in some foreign country.

CENSER, in antiquity, a vase containing incense to be used in sacrifices. Censer is chiefly used in speaking

Cement
Censer.

Censio
||
Censor.Censor
||
Census.

ing of the Jewish worship. Among the Greeks and Romans it is more frequently called *thuribulum*, *θυσαντήριον*, and *acerra*.

The Jewish censor was a small sort of chafing-dish, covered with a dome, and suspended by a chain. Josephus tells us, that Solomon made twenty thousand gold censers for the temple of Jerusalem, to offer perfumes in, and fifty thousand others to carry fire in.

CENSIO, in antiquity, the act or office of the censor. See CENSUS.

Censio included both the rating or valuing a man's estate, and the imposing mulcts and penalties.

CENSIO *hastaria*, a punishment inflicted on a Roman soldier for some offence, as laziness or luxury, whereby his *hasta* or spear was taken from him, and consequently his wages and hopes of preferment stopped.

CENSITUS, a person censured, or entered in the censual tables. See CENSUS.

In an ancient monument found at Ancyra, containing the actions of the emperor Octavius, we read,

*Quo lustro civium Romanorum
Censiti sunt capita quadragies
Centum millia & sexaginta tria.*

CENSITUS is also used in the civil law for a servile sort of tenant, who pays capitation to his lord for the land he holds of him, and is entered as such in the lord's rent-roll. In which sense, the word amounts to the same with *capite census*, or *capite censitus*. See *CAPITE Censi*.

CENSOR, (from *censere* to "see" or "perceive"), one of the prime magistrates in ancient Rome.—Their business was to register the effects of the Roman citizens, to impose taxes in proportion to what each man possessed, and to take cognizance or inspection of the manners of the citizens. In consequence of this last part of their office, they had a power to censure vice or immorality by inflicting some public mark of ignominy on the offender. They had even a power to create the *princeps senatus*, and to expel from the senate such as they deemed unworthy of that office. This power they sometimes exercised without sufficient grounds; and therefore a law was at length passed, that no senator should be degraded or disgraced in any manner, until he had been formally accused and found guilty by both the censors. It was also a part of the censorian jurisdiction, to fill up the vacancies in the senate, upon any remarkable deficiency in their number; to let out to farm all the lands, revenues, and customs, of the republic; and to contract with artificers for the charge of building and repairing all the public works and edifices both in Rome and the colonies of Italy. In all parts of their office, however, they were subject to the jurisdiction of the people; and an appeal always lay from the sentence of the censors to that of an assembly of the people.

The first two censors were created in the year of Rome 311, upon the senate's observing that the consuls were so much taken up with war, as not to have time to look into other matters. The office continued to the time of the emperors, who assumed the censorial power, calling themselves *morum præfetti*; though Vespasian and his sons took the title of censors. Decius attempted to restore the dignity to a particular

magistrate. After this we hear no more of it, till Constantine's time, who made his brother censor, and he seems to have been the last that enjoyed the office.

The office of censor was so considerable, that for a long time none aspired to it till they had passed all the rest; so that it was thought surprising that Crassus should be admitted censor, without having been either consul or prætor. At first the censors enjoyed their dignity for five years, but in 420 the dictator Mamerinus made a law restraining it to a year and an half, which was afterwards observed very strictly. At first one of the censors was elected out of a patrician, and the other out of a plebeian family; and upon the death of either, the other was discharged from his office, and two new ones elected, but not till the next lustrum. In the year of Rome 622, both censors were chosen from among the plebeians; and after that time the office was shared between the senate and people.—After their election in the Comitia Centuriaria, the censors proceeded to the capitol, where they took an oath not to manage either by favour or disaffection, but to act equitably and impartially throughout the whole course of their administration.

The republic of Venice still has a censor of the manners of their people, whose office lasts six months.

CENSORS of Books, are a body of doctors or others established in divers countries, to examine all books before they go to the press, and to see they contain nothing contrary to faith and good manners.

At Paris, the faculty of theology claim this privilege, as granted to them by the pope; but, in 1624, new commissions of four doctors were created, by letters-patent, the sole censors of all books, and answerable for every thing contained therein.

In England, we had formerly an officer of this kind, under the title of licenser of the press: but, since the revolution, our press has been laid under no such restraint.

CENSORINUS, a celebrated writer in the third century, well known by his treatise *De Die Natali*. This treatise, which was written about the year 238, Gerard Vossius calls a little book of gold; and declares it to be a most learned work of the highest use and importance to chronologers, since it connects and determines, with great exactness, some of the principal æras in pagan history. It was printed at Cambridge, with the notes of Lindenbrokius, in 1695.

CENSURE, a judgment which condemns some book, person, or action, or, more particularly, a reprimand from a superior. Ecclesiastical censures are penalties by which, for some remarkable misbehaviour, Christians are deprived of the communion of the church, or prohibited to execute the sacerdotal office.

CENSUS, in Roman antiquity, an authentic declaration made before the censors, by the several subjects of the empire, of their respective names and places of abode. This declaration was registered by the censors; and contained an enumeration, in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, wives, children, domestics, tenants, slaves. In the provinces the census served not only to discover the substance of each person, but where, and in what manner and proportion, taxes might be best imposed. The census at Rome is common-

ly

Census,
Cent.

ly thought to have been held every five years; but Dr Middleton hath shown, that both census and lustrum were held irregularly and uncertainly at various intervals. The census was an excellent expedient for discovering the strength of the state: for by it they discovered the number of the citizens, how many were fit for war, and how many for offices of other kinds; how much each was able to pay of taxes, &c. It went through all ranks of people, though under different names: that of the common people was called *census*; that of the knights, *census*, *recensio*, *recognitio*; that of the senators, *lectio*, *relectio*.—Hence also *census* came to signify a person who had made such a declaration; in which sense it was opposed to *incensus*, a person who had not given in his estate, or name, to be registered.

The census, according to Salmasius, was peculiar to the city of Rome. That in the provinces was properly called *profectio* and *ἀπογραφή*. But this distinction is not every where observed by the ancients themselves.

CENSUS was also used for the book or register wherein the professions of the people were entered: In which sense, the census was frequently cited and appealed to, as evidence in the courts of justice.

CENSUS is also used to denote a man's whole substance or estate.

CENSUS *Senatorius*, the patrimony of a senator, which was limited to a certain value; being at first rated at eight hundred thousand sesterces, but afterwards, under Augustus, enlarged to twelve hundred thousand.

CENSUS *Equestris*, the estate or patrimony of a knight, rated at four hundred thousand sesterces, which was required to qualify a person for that order, and without which no virtue or merit was available.

CENSUS was also used for a person worth an hundred thousand sesterces, or who was entered as such in the censual tables, on his own declaration. In which sense, census amounts to the same with *classicus*, or a man of the first class; though Gellius limits the estate of those of this class to an hundred and twenty-five thousand asses. By the Voconian law, no census was allowed to give by his will above a fourth part of what he was worth to a woman.

CENSUS was also used to denote a tax or tribute imposed on persons, and called also capitation. See *CAPITE Censu*.

CENSUS *Dominicus*, in writers of the lower age, denotes a rent due to the lord.

CENSUS *Duplicatus*, a double rent or tax, paid by vassals to their lord on extraordinary or urgent occasions; as expeditions to the Holy Land, &c.

CENSUS *Ecclesiæ Romanæ*, was an annual contribution voluntarily paid to the see of Rome by the several princes of Europe.

CENT, signifies properly an hundred, being an abridgement of the word *centum*; but is often used in commerce to express the profit or loss arising from the sale of any commodity: so that when we say there is 10 per cent. profit, or 10 per cent. loss, upon any merchandize that has been sold, it is to be understood, that the seller has either gained or lost ten pounds on every hundred pounds of the price at which he bought that merchandize; which is $\frac{1}{10}$ of profit, or $\frac{1}{10}$ of loss, upon the total of the sale.

N^o 68.

CENTAUREA, in botany: A genus of the polygamia frustanea order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is bristly; the pappus simple; the corollulæ of the radius funnel-shaped, longer than those of the disk, and irregular.

CENTAUR, in astronomy, a part or moiety of a southern constellation, in form half-man half-horse; usually joined with the wolf. The word comes from *κентаυρος*, formed of *κέντιον*, *pungo*; and *ταυρος*, *bull*; q. d. *bull-pricker*. The stars of this constellation, in Ptolemy's Catalogue are 37; in Tycho's 4; and in the Britannic Catalogue, with Sharp's Appendix, 35.

CENTAURS, in mythology, a kind of fabulous monsters, half men and half horses.—The poets pretend that the centaurs were the sons of Ixion and a cloud; the reason of which fancy is, that they retired to a castle called *νεβηλα*, which signifies a "cloud."—This fable is differently interpreted: some will have the centaurs to have been a body of shepherds and herdsmen, rich in cattle, who inhabited the mountains of Arcadia, and to whom is attributed the invention of bucolic poetry. Palæphætus, in his book of incredible, relates, that under the reign of Ixion, king of Thessaly, a herd of bulls on mount Thessaly run mad, and ravaged the whole country, rendering the mountains inaccessible; that some young men who had found the art of taming and mounting horses, undertook to clear the mountains of these animals, which they pursued on horseback, and thence obtained the appellation of *Centaurs*. This success rendering them insolent, they insulted the Lapithæ, a people of Thessaly: and because when attacked they fled with great rapidity, it was supposed they were half horses and half men.—The Centaurs in reality were a tribe of Lapithæ, who inhabited the city Pelethronium adjoining to mount Pelion, and first invented the art of breaking horses, as is intimated by Virgil.

CENTAUREA, GREATER CENTAURY: A genus of the polygamia frustanea order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is bristly, the pappus simple, the corollulæ of the radius funnel-shaped, longer than those of the disk, and irregular. There are 61 species. The root of one of them called *glastifolia*, is an article in the materia medica. It has a rough, somewhat acrid taste, and abounds with a red viscid juice. Its rough taste has gained it some esteem as an astringent; its acrimony as an aperient; and its glutinous quality as a vulnerary: but the present practice takes very little notice of it in any intention. Another of the species is the cyanus or blue bottle, which grows commonly among corn. The expressed juice of this flower stains linen of a beautiful blue colour, but is not permanent. Mr Boyle says, that the juice of the inner petals, with a little alum, makes a beautiful permanent colour, equal to ultramarine.

Lesser CENTAURY. See GENTIANA.

CENTELLA, in botany: A genus of the tetrandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 11th order, *Sarmentaceæ*. The male involucre is tetraphyllous and quinqueflorous, with four petals; the female

Centaurea

Centiloqui- lar seed-case.
um.

CENTENARIUS, or **CENTENARIO**, in the middle age, an officer who had the government or command, with the administration of justice, in a village. The *centenarii* as well as *vicarii* were under the jurisdiction and command of the court. We find them among the Franks, Germans, Lombards, Goths, &c.

CENTENARIUS was also used for an officer who had the command of 100 men; most frequently called a **CENTURION**.

CENTENARIUS, in monasteries, was an officer who had the command of 100 monks.

CENTENINUM OVUM, among naturalists, denotes a sort of hen's egg much smaller than ordinary, vulgarly called a *cock's egg*; from which it has been fabulously held that the cockatrice or basilisk is produced. The name is taken from an opinion, that these are the last eggs which hens lay, having laid 100 before; whence *centeninum*, q. d. the hundredth egg.—These eggs have no yolks, but in other respects differ not from common ones; having the albumen, chalazas, membranes, &c. in common with others. In the place of the yolk is found a little body like a serpent coiled up, which doubtless gave rise to the fable of the basilisk's origin from thence. Their origin is with probability ascribed by Hervey to this, that the yolks in the vitellary of the hen are exhausted before the albumina.

CENTER, or **CENTRE**, in a general sense, signifies a point equally distant from the extremities of a line, figure, or body. The word is formed from the Greek *κέντρον*, a point.

CENTER of Gravity, in mechanics, that point about which all the parts of a body do in any situation exactly balance each other.

CENTER of Motion, that point which remains at rest, while all the other parts of a body move about it.

CENTER of a Sphere, a point in the middle, from which all lines drawn to the surface are equal.

Hermes Trismegistus defines God an intellectual sphere, whose center is every where, and circumference no where.

CENTESIMA USURA, that wherein the interest in an hundred months became equal to the principal; i. e. where the money is laid out at one *per cent.* per month; answering to what in our style would be called 12 *per cent.* for the Romans reckoned their interest not by the year, but by the month.

CENTESIMATION, a milder kind of military punishment, in cases of desertion, mutiny, and the like, when only every hundredth man is executed.

CENTILOQUIUM, denotes a collection of 100 sentences, opinions, or sayings.

The centiloquium of Hermes, contains 100 aphorisms, or astrological sentences, supposed to have been written by some Arab, falsely fathered on Hermes Trismegistus. It is only extant in Latin, in which it has several times been printed.—The centiloquium of Ptolomy is a famous astrological piece, frequently confounded with the former, consisting likewise of 100 sentences, or doctrines, divided into short aphorisms, intitled also in Greek *κατακευ*, as being the fruit or re-

sult of the former writings of that celebrated astronomer, viz. his *quadripartitum* and *almagestum*; or rather, by reason that herein is shown the use of astrological calculations.

CENTIPES, in zoology. See **SCOLOPENDRA**.

CENTIPED WORM, a term used for such worms as have a great many feet, though the number does not amount to 100, as the term seems to import.—M. Maloet relates the history of a man, who, for three years, had a violent pain in the lower part of the forehead near the root of the nose: at length he felt an itching, and afterwards something moving within his nostril, which he brought away with his finger; it was a worm of the centiped kind, an inch and an half long, which run swiftly. It lived five or six days among tobacco. The patient was free of his pain ever after. Mr Littre mentioned a like case in 1708, of a larger centiped voided at the nose, after it had thrown the woman, in whose frontal sinus it was, into convulsions, and had almost deprived her of her reason.

CENTLIVRE (Susanna), a celebrated comic writer, was the daughter of Mr Freeman of Holbeach, in Lincolnshire; and had such an early turn for poetry, that it is said she wrote a song before she was seven years old. Before she was twelve years of age, she could not only read Moliere in French, but enter into the spirit of all the characters. Her father dying, left her to the care of a step-mother; whose treatment not being agreeable to her, she determined, though almost destitute of money and every other necessary, to go up to London to seek a better fortune than what she had hitherto experienced. As she was proceeding on her journey on foot, she was met by a young gentleman from the university of Cambridge, the afterwards well-known Anthony Hammond, Esq; who was so extremely struck with her youth and beauty, that he fell instantly in love with her; and inquiring into the particulars of her story, soon prevailed upon her unexperienced innocence to seize on the protection he offered her, and go with him to Cambridge. After some months cohabitation, he persuaded her to come to London; where, in a short time, she was married to a nephew of Sir Stephen Fox. But that gentleman not living with her above a twelvemonth, her wit and beauty soon procured her a second husband, whose name was Carrol, and who was an officer in the army; but he having the misfortune to be killed in a duel about a year and an half after their marriage, she became a second time a widow. For the sake of support she now applied to her pen, and became a votary of the muses; and it is under this name of Carrol that some of her earlier pieces were published. Her first attempt was in tragedy, in a play called the *Perjured Husband*; yet her natural vivacity leading her afterwards to comedy, we find but one more attempt in the bufkin, among 18 dramatic pieces which she afterwards wrote.

In 1706, she wounded the heart of one Mr Joseph Centlivre, yeoman of the mouth, or in other words principal cook to her Majesty, who married her; and, after passing several years happily together, she died at his house in Spring-Garden, Charing-Cross, in December 1723.

Centipes
Centlivre.

Centner.

This lady for many years enjoyed the intimacy and esteem of the most eminent wits of the times, viz. Sir Richard Steele, Mr Rowe, Budgell, Farquhar, Dr Sewell, &c. and very few authors received more tokens of esteem and patronage from the great. With regard to her merit as a writer, it must be allowed that her plays do not abound with wit, and that the language of them is sometimes even poor, enervate, incorrect, puerile; but then her plots are busy and well conducted, and her characters in general natural and well marked.

CENTNER, or DOCIMASTIC HUNDRED, in metallurgy and assaying, is a weight divisible, first into an hundred, and thence into a greater number of other smaller parts; but though the word is the same both with the assayers and metallurgists, yet it is to be understood as expressing a very different quantity in their different acceptation of it. The weights of the metallurgists are easily understood, as being of the common proportion, but those of the assayers are a thousand times smaller than these, as the portions of metals or ores examined by the assayers are usually very small.

The metallurgists, who extract metals out of their ores, use a weight divided into an hundred equal parts, each part a pound; the whole they call a *centner* or *hundred weight*; the pound is divided into thirty-two parts, or half ounces: and the half ounce into two quarters of ounces, and these each into two drams.

These divisions and denominations of the metallurgists are easily understood; but the same words, tho' they are equally used by assayers, with them express very different quantities; for as the centner of the metallurgists contains an hundred pounds, the centner of the assayers is really no more than one dram, to which the other parts are proportioned.

As the assayers weights are divided into such an extreme degree of minuteness, and are so very different from all the common weights, the assayers usually make them themselves in the following manner, out of small silver, or fine folder plates, of such a size, that the mark of their weight, according to the division of the dram, which is the *docimastic* or assaying *centner*, may be put upon them. They first take for a basis one weight, being about two-thirds of a common dram: this they mark (64*lb.*) Then having at hand some granulated lead, washed clean, well dried, and sifted very fine, they put as much of it into one of the small dishes of a fine balance as will equipoise the (64*lb.*) as it is called, just mentioned: then dividing this granulated lead into very nice halves, in the two scales, after taking out the first silver weight, they obtain a perfect equilibrium between the two scales; they then pour the granulated lead out of one dish of the scales, and instead of it put in another silver weight, which they make exactly equiponderant with the lead in the other scale, and mark it (32*lb.*) If this second weight, when first put into the scale, exceed by much the weight of the lead, they take a little from it by a very fine file; but when it comes very near, they use only a whetstone to wear off an extremely small portion at a time. When it is brought to be perfectly even and equal to the lead, they change the scales to see that no error has been committed, and then go on in the same manner till they have made all the divisions, and all

the small weights. Then to have an entire centner or hundred weight, they add to the (64*lb.*) as they call it, a 32*lb.* and a 4*lb.* and weighing against them one small weight, they make it equal to them, and mark it (100.) This is the docimastical, or assaying centner, and is really one dram.

CENTO, in poetry, a work wholly composed of verses or passages promiscuously taken from other authors, only disposed in a new form and order.—Proba Falconia has written the life of Jesus Christ in centos taken from Virgil. Alexander Ross has done the like in his *Christados*, and Stephen de Pleure the same.

CENTONARI, in antiquity, certain of the Roman army, who provided different sorts of stuff called centones, made use of to quench the fire which the enemies engines threw into the camp.

These centonarii kept with the carpenters and other officers of artillery.

CENTRAL FORCES, the powers which cause a moving body to tend towards, or recede from, the center of motion. See MECHANICS.

CENTRAL Rule, a rule discovered by Mr Thomas Baker, whereby to find the centre of a circle designed to cut the parabola in as many points as an equation to be constructed hath real roots. Its principal use is in the construction of equations, and he hath applied it with good success as far as biquadratics.

The central rule is chiefly founded on this property of the parabola, that, if a line be inscribed in that curve perpendicular to any diameter, a rectangle formed of the segments of the inscript is equal to the rectangle of the intercepted diameter and parameter of the axis.

The central rule has the advantage over Cartes and De Latere's methods of constructing equations, in that both these are subject to the trouble of preparing the equation by taking away the second term.

CENTRIFUGAL FORCE, that force by which all bodies that move round any other body in a curve endeavour to fly off from the axis of their motion in a tangent to the periphery of the curve, and that in every part of it. See MECHANICS.

CENTRIFUGAL-Machine, a very curious machine, invented by Mr Erskine, for raising water by means of a centrifugal force combined with the pressure of the atmosphere.

It consists of a large tube of copper, &c. in the form of a cross, which is placed perpendicular in the water, and rests at the bottom on a pivot. At the upper part of the tube is a horizontal cog-wheel, which touches the cogs of another in a vertical position; so that by the help of a double winch, the whole machine is moved round with very great velocity.

Near the bottom of the perpendicular part of the tube is a valve opening upwards; and near the two extremities, but on the contrary sides of the arms, or cross part of the tube, are two other valves opening outwards. These two valves are, by the assistance of springs, kept shut till the machine is put in motion, when the centrifugal velocity of the water forces them open, and discharges itself into a cistern or reservoir placed there for that purpose.

On the upper part of the arms are two holes, which are

Cento
||
Centrifugal.

Centrifugal.

are closed by pieces screwing into the metal of the tube. Before the machine can work, these holes must be opened, and water poured in through them, till the whole tube be full: by this means all the air will be forced out of the machine, and the water supported in the tube by means of the valve at the bottom.

The tube being thus filled with water, and the holes closed by their screw caps, it is turned round by means of the winch, when the water in the arms of the tube acquires a centrifugal force, opens the valves near the extremities of the arms, and flies out with a velocity nearly equal to that of the extremities of the said arms.

The above description will be very easily understood by the figure we have added on Plate CXXXVI. which is a perspective view of the centrifugal machine, erected on board a ship. ABC is the copper tube. D, a horizontal cog-wheel, furnished with twelve cogs. E, a vertical cog-wheel, furnished with thirty-six cogs. F, F, the double winch. *a*, the valve near the bottom of the tube. *b, b*, the two pivots on which the machine turns. *c*, one of the valves in the cross-piece; the other at *d*, cannot be seen in this figure, being on the other side of the tube. *e, e*, the two holes through which the water is poured into the machine. GH, the cistern or reservoir. I, I, part of the ship's deck. The distance between the two valves, *c, d*, is six feet. The diameter of these valves is about three inches; and that of the perpendicular tube about seven inches.

If we suppose the men who work the machines can turn the winch round in three seconds, the machine will move round its axis in one second; and consequently each extremity of the arms will move with a velocity of 18.8 feet in a second. Therefore a column of water of three inches diameter will issue through each of the valves with a velocity of 18.8 feet in a second: but the area of the aperture of each of the valves is 7.14 inches; which being multiplied by the velocity in inches = 225.6, gives 1610.784 cubic inches, the quantity of water discharged through one of the apertures in one second; so that the whole quantity discharged in that space of time through both the apertures is = 3221.568 inches; or 193294.08 cubic inches in one minute. But 60812 cubic inches make a tun, beer-measure; consequently, if we suppose the centrifugal machine revolves round its axis in one second, it will raise nearly 3 tuns 44 gallons in one minute: but this velocity is certainly too great, at least to be held for any considerable time; so that, when this and other deficiencies in the machine are allowed for, two tuns is nearly the quantity that can be raised by it in one minute.

It will perhaps be unnecessary to observe, that as the water is forced up the perpendicular tube by the pressure of the atmosphere, this machine cannot raise water above 32 feet high.

An attempt was made to substitute this machine in place of the pumps commonly used on ship-board, but the labour of working was found to be so great as to render the machine inferior to the chain-pump. A considerable improvement, we apprehend, would be, to load with a weight of lead the ends of the tubes thro' which the water issues, which would make the machine turn with a great deal more ease, as the centrifugal

force of the lead would in some measure act the part of a fly.

CENTRIPETAL FORCE, that force by which a body is every where impelled, or any how tends, towards some point as a centre. See MECHANICS.

CENTRISCUS, in ichthyology, a genus of fishes belonging to the order of amphibia nantes. The head gradually ends in a narrow snout, the aperture is broad and flat; the belly is carinated; and the belly-fins united. There are two species, viz. 1. The scutatus has its back covered with a smooth bony shell, which ends in a sharp spine under which is the tail; but the back fins are between the tail and the spine. It is a native of the East Indies. 2. The scolopax has a rough scabrous body, and a straight extended tail. It has two belly-fins, with four rays in each, and has no teeth. It is found in the Mediterranean.

CENTRONIA, in natural history, a name by which the echini marini have been lately distinguished. Dr Hill makes them a distinct class of animals living under the defence of shelly coverings formed of one piece, and furnished with a vast number of spines moveable at the creature's pleasure.

CENTUMCELLÆ, (anc. geog.), Trajan's villa in Tuscany, on the coast, three miles from Algæ; with an excellent port, called *Trajanus Portus*, (Ptolemy); and a factitious island at the mouth of the port, made with a huge block of stone, on which two turrets rose, with two entrances into the basin or harbour, Rutilius. Now *Civita Necchia*. E. Long. 12. 30. N. Lat. 42.

CENTUMVIRI, in Roman antiquity, judges appointed to decide common causes among the people: they were chosen, three out of each tribe; and though five more than an hundred, were nevertheless called *centumviri*, from the round number *centum*, an hundred.

CENTUNCULUS, in botany: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The calyx is quadrifid; the corolla quadrifid, and patent; the stamina are short; the capsule is unilocular, cut round, or parting horizontally.

CENTURION, among the Romans, an officer in the infantry, who commanded a century, or an hundred men.

In order to have a proper notion of the centurions, it must be remembered, that every one of the thirty manipuli * in a legion was divided into two *ordines*, or * See Manipulus. ranks; and consequently the three bodies of the hastati, principes, and triarii, into 20 orders a piece, as into 10 manipuli. Now, every manipulus was allowed two centurions, or captains, one to each order or century: and, to determine the point of priority between them, they were created at two different elections. The 30 who were made first always took the precedence of their fellows; and therefore commanded the right-hand orders, as the others did the left. The triarii, or *pilani*, so called from their weapon the *pilum*, being esteemed the most honourable, had their centurions elected first, next to them the principes, and afterwards the hastati; whence they were called *primus et secundus pilus*, *primus et secundus princeps*, *primus et secundus hastatus*; and so on. Here it may be observed, that *primi ordines* is sometimes used in historians for the centurions

Centurion
||
Century.

rions of these orders; and the centurions are sometimes styled *principes ordinum*, and *principes centurionum*. We may take notice too what a large field there lay for promotion: first through all the orders of the *hastati*; then quite through the *principes*; and afterwards from the last order of the *triarii* to the *primipilus*, the most honourable of the centurions, and who deserves to be particularly described. This officer, besides his title of *primipilus*, went under the several titles of *dux legionis*, *præfectus legionis*, *primus centurionum*, and *primus centurio*; and was the first centurion of the *triarii* in every legion. He presided over all the other centurions, and generally gave the word of command by order of the tribunes. Besides this, he had the care of the eagle, or chief standard, of the legion: hence, *aquila præfesse*, is to bear the dignity of *primipilus*; and hence *aquila* is taken by Pliny for the said office. Nor was this station only honourable, but very profitable too: for he had a special stipend allowed him, probably as much as a knight's estate; and, when he left that charge, was reputed equal to the members of the equestrian order, bearing the title of *primipilarius*, in the same manner as those who had discharged the greatest civil offices were styled ever after, *consulares*, *censorii*, &c.

CENTURIPÆ, CENTORIPA, or CENTURIPÆ, (anc. geog.), a town in the south-west of the territory of Etna, on the river Cyamaforus: Now *Centorbi*, or *Centurippi*. It was a democratical city, which, like Syracuse, received its liberty from Timoleon. Its inhabitants cultivated the fine arts, particularly sculpture and engraving. In digging for the remains of antiquities, cameos are no where found in such abundance as at Centurippi and its environs. The situation of the place is romantic: it is built on the summit of a vast group of rocks, which was probably chosen as the most difficult of access, and consequently the properest in times of civil commotion. The remains still existing of its ancient bridge are a proof of its having been a considerable city. Cicero speaks of it as such. It was taken by the Romans, plundered and oppressed by Verres, destroyed by Pompey, and restored by Octavius, who made it the residence of a Roman colony.

CENTURY, in a general sense, any thing divided into, or consisting of, an hundred parts.

The marquis of Worcester published a *Century* of inventions, (for a specimen of which, see ACOUSTICS, n° 27.); and Dr Hooke has given a *decimate* of inventions, as part of a *Century*, of which he affirmed himself master. It is remarkable, that both in the century of the former, and the decimate of the latter, we find the principle on which Savary's fire or steam engine is founded. See STEAM-Engine.

CENTURY in antiquity. The Roman people, when they were assembled for the electing of magistrates, enacting of laws, or deliberating upon any public affair, were always divided into centuries, and voted by centuries, in order that their votes might be the more easily collected, whence these assemblies were called *comitia centuriata*. The Roman cohorts were also divided into centuries. See CENTURION and COHORT.

CENTURY, in chronology, the space of one hundred years. This method of computing by centuries is generally observed in church history, commencing from

the time of our Saviour's incarnation: in which sense we say the first century, the second century, &c.

CENTURIES of Magdeburg, a famous ecclesiastical history, ranged into 13 centuries, carried down to the year 1298, compiled by several hundred protestants of Magdeburg, the chief of whom was Flacius Illyricus.

CENTUSSIS, in Roman antiquity, a coin containing 100 asses.

CENTZONTLI, in ornithology, the Mexican name of the *Turdus polyglottus*. See TURDUS.

CEODES, in botany: A genus of the diœcia order, belonging to the polygamia class of plants. There is no calyx; the corolla is monopetalous, with a short turbinate tube; the stamina are ten subulated filaments; the antheræ roundish.

CEORLES, the name of one of the classes or orders into which the people were distinguished among the Anglo-Saxons. The ceorles, who were persons completely free, and descended from a long race of freemen, constituted a middle class between the labourers and mechanics (who were generally slaves, or descended from slaves) on the one hand, and the nobility on the other. They might go where they pleased, and pursue any way of life that was most agreeable to their humour; but so many of them applied to agriculture, and farming the lands of the nobility, that a ceorl was the most common name for a husbandman or farmer in the Anglo-Saxon times. These ceorls, however, seem in general to have been a kind of gentleman farmers; and if any one of them prospered so well as to acquire the property of five hydes of land, upon which he had a church, a kitchen, a bell-house, and great gate, and obtained a seat and office in the king's court, he was esteemed a nobleman or thane. If a ceorl applied to learning, and attained to priest's orders, he was also considered as a thane; his weregild, or price of his life, was the same, and his testimony had the same weight in a court of justice. When he applied to trade, and made three voyages beyond sea, in a ship of his own, and with a cargo belonging to himself, he was also advanced to the dignity of a thane. But if a ceorl had a greater propensity to arms than to learning, trade, or agriculture, he then became the sithcundman, or military retainer, to some potent and warlike earl, and was called the *huscarle* of such an earl. If one of these huscarles acquitted himself so well as to obtain from his patron either five hydes of land, or a gilt sword, helmet, and breastplate, as a reward of his valour, he was likewise considered as a thane. Thus the temple of honour stood open to these ceorls, whether they applied themselves to agriculture, commerce, letters, or arms, which were then the only professions esteemed worthy of a freeman.

CEOS, CEA, CIA, or Cos, (anc. geog.), one of the Cyclades, lies opposite to the promontory of Achaia called *Sunium*, and is 50 miles in compass. This island is commended by the ancients for its fertility and richness of its pastures. The first silk stuffs, if Pliny and Solinus are to be credited, were wrought here. Ceos was particularly famous for the excellent figs it produced. It was first peopled by Aristæus, the son of Apollo and Cyrene, who, being grieved for the death of his son Actæon, retired from Thebes, at the persuasion of his mother, and went over with some Thebans

Cephalenia.

bans to Ceos, at that time uninhabited. Diodorus Siculus tells us, that he retired to the island of Cos; but the ancients, as Servius observes, called both these islands by the name of Cos. Be that as it will, the island of Ceos became so populous, that a law prevailed there, commanding all persons upwards of sixty to be poisoned, that others might be able to subsist; so that none above sixty were to be seen in the island, being obliged, after they arrived at that age, either to submit to the law, or abandon the country, together with their effects. Ceos had, in former times, four famous cities, viz. Julis, Carthæa, Coreffus, and Præessa. The two latter were, according to Pliny, swallowed up by an earthquake. The other two flourished in Strabo's time. Carthæa stood on a rising ground, at the end of a valley, about three miles from the sea. The situation of it agrees with that of the present town of Zia, which gives name to the whole island. The ruins both of Carthæa and Julis are still remaining; those of the latter take up a whole mountain, and are called by the modern inhabitants Polis, that is, *the city*. Near this place are the ruins of a stately temple, with many pieces of broken pillars, and statues of most exquisite workmanship. The walls of the city were of marble, and some pieces are still remaining above 12 feet in length. Julis was, according to Strabo, the birth-place of Simonides, Bacchylides, Erastriatus, and Aristo. The Oxford marbles tell us, that Simonides, the son of Leoprepis, invented a sort of artificial memory, the principles of which he explained at Athens, and add, that he was descended of another Simonides, who was a poet no less renowned than himself. One of these two poets invented those melancholy verses which were sung at funerals, and are called by the Latins *neniae*. Strabo says, that the Athenians, having besieged the city of Julis, raised the siege, upon advice that the inhabitants had resolved to murder all the children under a certain age, that useful persons might not be employed in looking after them. Ceos was, with the other Greek islands, subdued by the Romans, and bestowed upon the Athenians by Marc Antony the triumvir, together with Ægina, Tinos, and some other adjoining islands, which were all reduced to one Roman province by Vespasian. The island is now called *Zea*.

CEPA, the ONION. See ALLIUM.

CEPHALANTHUS, BUTTON-WOOD: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 48th order, *Aggregate*. There is no common calyx; the proper one is superior, and funnel-shaped; the receptacle globose and naked, with one downy seed. There is only one species, the *Occidentalis*; a deciduous shrub, native of north America. It grows to about five or six feet high; and is not a very bushy plant, as the branches are always placed thinly in proportion to the size of the leaves, which will grow more than three inches long, and one and a half broad, if the trees are planted in a soil they like. The leaves stand opposite by pairs on the twigs, and also sometimes by threes, and are of a light-green colour: Their upper surface is smooth; they have a strong nerve running from the footstalk to the point, and several others from that on each side to the borders: These, as well as the footstalks, in the au-

tumn dye to a reddish colour. The flowers, which are aggregate flowers, properly so called, are produced at the ends of the branches, in globular heads, in July. The florets which compose these heads are funnel-shaped, of a yellow colour, and fastened to an axis which is in the middle.—The cephalanthus is propagated from seeds, which we receive from America. These should be sown as soon as they arrive, and there will be a chance of their coming up the first spring; though they often lie till the spring after before they make their appearance. They may be sown in good garden mould of almost any soil, if somewhat moist the better, and should be covered about a quarter of an inch deep. This shrub is also propagated by layers. If the young shoots are laid in autumn, they will have struck good root by the autumn following, and may be then taken up, and set in the places where they are designed to remain. Cuttings of this tree, also, planted in the autumn in a rich, light, moist soil, will grow: and by that means also plenty of these plants may be soon obtained.

CEPHALIC, in a general meaning, signifies any thing belonging to the head.

CEPHALIC Medicines, are remedies for disorders of the head. Cordials are comprehended herein, as are also whatever promotes a free circulation of the blood through the brain.

Except when the disorder arises from excess of heat, or an inflammatory disposition in the head, moist topicals should never be used; but always dry ones.

To rub the head after it is shaved proves an instantaneous cure for a cephalalgia, a stuffing of the head, and a weakness of the eyes, arising from a weak and relaxed state of the fibres. And as by every fresh evacuation of the humours their quantity is not only lessened, but also their recrementitious parts derived thither, the more frequently the head is shaved, the larger quantity of humour is discharged; so that the frequent shaving of the head and beard is likewise a perpetual blister; and in as much as it is useful, it is a cephalic.

CEPHALIC Vein, in anatomy, creeps along the arm between the skin and the muscles, and divides it into two branches: the external goes down to the wrist, where it joins the basilica, and turns up to the back of the hand; the internal branch, together with a small one of the basilica, makes the mediana.

The ancients used to open this vein for disorders of the head, for which reason it bears this name; but a better acquaintance with the circulation of the blood informs us, that there is no foundation for such a notion.

CEPHALENIA, or CEPHALLENIA, an island of the Ionian sea between Ithaca and Zacynthus, known in Homer's time by the names of Samus and Epirus Melæna, is about eighty miles in length, forty in breadth, and a hundred and thirty in compass. It had anciently four cities, one of which bore the name of the island. Strabo tells us, that in his time there were only two cities remaining; but Pliny speaks of three; adding, that the ruins of Same, which had been destroyed by the Romans, were still in being. Same was the metropolis of the island, and is supposed to have stood in the place which the Italians call Porto Guiscardo. The names of the four cities were, according-

ing

Cephalonia
||
Ceratocarpus.

ing to Thucydides, Same, Prone, Crani, and Palæ. This island was subdued by the Thebans, under the conduct of Amphitryo, who is said to have killed Pterelas, who then reigned here. While Amphitryo was carrying on the war in Cephalenia, then called Samos, one Cephalus, a man of great distinction at Athens, having accidentally killed his wife Procris in shooting at a deer, fled to Amphitryo, who, pitying his case, not only received him kindly, but made him governor of the island, which thenceforth was called Cephalenia. After it had been long in subjection to the Thebans, it fell under the power of the Macedonians, and was taken from them by the Ætolians, who held it till it was reduced by M. Fulvius Nobilior, who, having gained the metropolis after a four months siege, sold all the citizens for slaves, adding the whole island to the dominions of his republic. Now called CEPHALONIA.

CEPHALONIA, the capital of an island of the same name, situated in the Mediterranean, near the coast of Epirus, and subject to the Venetians. E. Long. 21. N. Lat. 30. 30.

CEPHEUS, in fabulous history, a king of Arcadia, on whose head Minerva fastening one of Medusa's hairs, he was rendered invincible.

CEPHEUS, in astronomy, a constellation of the northern hemisphere. See ASTRONOMY, n° 406.

CERAM, an island in the Indian ocean, between the Molucca islands on the north, and those of Ambona and Banda on the south, lying between E. Long. 126. and 129. in S. Lat. 3. It is about 150 miles long, and 60 broad; and here the Dutch have a fortress, which keeps the natives in subjection.

CERAMBYX, in zoology, a genus of insects of the beetle kind, belonging to the order of insecta coleopatera. The antennæ are long and small; the breast is spinous or gibbous; and the elytra are linear. There are no less than 83 species enumerated by Linnæus, principally distinguished by the figure of the breast.

CERASTES, in zoology, the trival name of a species of ANGUIS and COLUBER.

CERASTIUM, MOUSE-EAR: A genus of the pentagynia order, belonging to the decandria class of plants; and in the natural method ranking under the 22d order, *Caryophyllæa*. The calyx is pentaphyllous; the petals are bifid; the capsule is unilocular, and opening at the top. There are 16 species, but none of them possessed of any remarkable property.

CERASUS, in botany. See PRUNUS.

CERATE, in pharmacy, a thickish kind of ointment, applied to ulcerations, excoriations, &c. See PHARMACY, *Index*.

CERATION, the name given by the ancients to the small seeds of Ceratonia, used by the Arabian physicians as a weight to adjust the doses of medicines; as the grain weight with us took its rise from a grain of barley.

CERATON, or *ceratium*, was also a silver coin, equal to one third of an obolus.

CERATOCARPUS, in botany: A genus of the monandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 12th order, *Holoraceæ*. The male calyx is bipartite;

there is no corolla; the filament is long; The female calyx is diphyllous, and grown to the germen; there is no corolla; the styles are two; the seed is two-horned and compressed.

CERATONIA, the CAROB TREE, or *St John's-bread*: A genus of the polyœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 33d order, *Lomentaceæ*. The calyx is hermaphrodite and quinquepartite; there is no corolla; the stamina are five; the style is filiform; the legumen coriaceous and polyspermous. It is also diœcious, or male and female distinct on different plants. There is but one species, the filiqua, a native of Spain, of some parts of Italy, and the Levant. It is an ever-green; and, in the countries where it is native, grows in the hedges. It produces a quantity of long, flat, brown-coloured pods, which are thick, mealy, and of a sweetish taste. These pods are many times eaten by the poorer sort of inhabitants when there is a scarcity of other food; but they are apt to loosen the belly, and cause gripings of the bowels. They are called *St John's-bread*, from an ill-founded assertion of some writers on Scripture, that these pods were the locusts St John eat with his honey in the wilderness. The tree may be propagated in this country from seeds, which are to be sown in a moderate hot-bed, and the plants inured to the open air by degrees.

CERATOPHYLLUM, in botany: A genus of the polyandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 15th order, *Inundata*. The male calyx is multipartite; no corolla; stamina from 16 to 20: The female calyx is multipartite; no corolla; one pistil; no style; one naked seed.

CERAUNIA, CERAUNIAS, or CERAUNIUS *Lapis*, in natural history, a sort of flinty stone, of no certain colour, but of a pyramidal or wedge-like figure; popularly supposed to fall from the clouds in the time of thunder-storms, and to be possessed of divers notable virtues, as promoting sleep, preserving from lightning, &c. The word is from the Greek *κεραυνος*, *thunderbolt*. The ceraunia is the same with what is otherwise called the thunder-stone, or thunder-bolt; and also sometimes *sagitta*, or arrow's-head, on account of its shape. The cerauniæ are frequently confounded with the ombriæ and brontia, as being all supposed to have the same origin. The generality of naturalists take the ceraunia for a native stone, formed among the Pyrites, of a saline, concrete, mineral juice. Mercatus and Dr Woodward assert it to be artificial, and to have been fashioned thus by tools. The ceraunia, according to these authors, are the heads of the ancient weapons of war, in use before the invention of iron; which, upon the introduction of that metal, growing into disuse, were dispersed in the fields through this and that neighbouring country. Some of them had possibly served in the early ages for axes, others for wedges, others for chisels; but the greater part for arrow-heads, darts, and lances. The ceraunia is also held by Pliny for a white or crystal-coloured gem, that attracted lightning to itself. What this was, is hard to say. Prudentius also speaks of a yellow ceraunia; by which he is supposed to mean the carbuncle or pyropus.

CERBERA, in botany: A genus of the monogynia

Ceratonia
||
Ceraunia.

Cerberus
||
Cercis.

Cercis.

nia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, *Contorta*. The fruit is a monospermous plem. The most remarkable species is the *atruncir*, a native of the warm parts of America. It rises with an irregular stem to the height of eight or ten feet, sending out many crooked diffused branches, which towards their tops are garnished with thick succulent leaves of a lucid green, smooth, and very full of a milky juice. The flowers come out in loose bunches at the end of the branches; they are of a cream colour, having long narrow tubes, and at the top are cut into five obtuse segments, which seem twisted, so as to stand oblique to the tube. The wood of this tree stinks most abominably, and the kernels of the nuts are a deadly poison to which there is no antidote; so that the Indians will not even use the wood for fuel.

CERBERUS, in fabulous history, a dreadful three-headed mastiff, born of Typhon and Echidna, and placed to guard the gates of hell. He fawned upon those who entered, but devoured all who attempted to get back. He was, however, mastered by Hercules, who dragged him up to the earth, when, in struggling, a foam dropped from his mouth, which produced the poisonous herb called *aconite* or *wolf's-bane*.

Some have supposed that Cerberus is the symbol of the earth, or of all-devouring time; and that its three mouths represent the present, past, and future. The victory obtained by Hercules over this monster, denotes the conquest which this hero acquired over his passions. Dr Bryant supposes that Cerberus was the name of a place, and that it signified the temple of the Sun; deriving it from *Kir-Abor*, the place of light. This temple was also called *Tor-Caph-El*, which was changed to *τρικεφαλος*; and hence Cerberus was supposed to have had three heads. It was likewise called *Tor-Keren*, *Turris Regia*; whence *τρι κεφαλος*, from *τρις*, three, and *κεφαλον*, head.

CERCELE, in heraldry: a cross cerecele is a cross which, opening at the ends, turns round both ways like a ram's horn. See **CROSS**.

CERCIS, the JUDAS-TREE: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 33d order, *Lomentaceae*. The calyx is quinque-dentated, and gibbous below; the corolla papilionaceous, with a short vexillum or flag-petal under the wings or side-petals; a leguminous plant. There are only two species, both deciduous.

1. The *siliquastrum*, common Judas-tree, or Italian cercis, a native of Italy and other parts of the south of Europe.—These differ in the height of their growth in different places: In some they will arrive to be fine trees, of near twenty feet high; whilst in others they will not rise to more than ten or twelve feet, sending forth young branches irregularly from the very bottom. The stem of this tree is of a dark-greyish colour, and the branches, which are few and irregular, have a purplish cast. The leaves are smooth, heart-shaped, and roundish, of a pleasant green on their upper surface, hoary underneath, and grow alternately on long footstalks. The flowers are of a fine purple: They come out early in the spring, in clusters, from the side of the branches, growing upon

short footstalks; and in some situations they are succeeded by long flat pods, containing the seeds, which, in very favourable seasons, ripen in England. Some people are fond of eating these flowers in fallads, on which account alone in some parts this tree is propagated. The varieties of this species are, 1. The Flesh-coloured; 2. The White-flowered; and, 3. The Broad-podded Judas-tree.

2. The *Canadensis*, or Canadian cercis, will grow to the size of the first sort in some places. The branches are also irregular. The leaves are cordated, downy, and placed alternately. The flowers usually are of a palish red colour, and show themselves likewise in the spring, before the leaves are grown to their size. These too are often eaten in fallads, and afford an excellent pickle. There is a variety of this with deep red, and another with purple flowers. The pleasure which these trees will afford in a plantation may be easily conceived, not only as they exhibit their flowers in clusters, in different colours, early in the spring, before the leaves are grown to such a size as to hide them; but from the difference of the upper and lower surface of the leaves; the one being of a fine green, the other of a hoary cast; so that on the same tree, even in this respect, is shown variety; an improvement whereof is made by the waving winds, which will present them alternately to view.

Propagation. As these species will not take root by layers, they must be propagated by seeds, which may be had from abroad. They are generally brought us found and good, and may be sown in the months of February or March. Making any particular compost for their reception is unnecessary; common garden mould, of almost every sort, will do very well: And this being well dug, and cleared of all roots, weeds, &c. lines may be drawn for the beds. The mould being fine, part of it should be taken out, and sifted over the seeds, after they are sown, about half an inch thick. Part of the seeds will come up in the spring, and the others will remain until the spring following; so that whoever is desirous of drawing the seedlings of a year old to plant out, must not destroy the bed, but draw them carefully out, and after that there will be a succeeding crop. However, be this as it will, the seeds being come up, they must be weeded, and encouraged by watering in the dry season; and they will require no farther care during the first summer. In the winter also they may be left to themselves, for they are very hardy; though not so much but that the ends of the branches will be killed by the frost, nay, sometimes to the very bottom of the young plant, where it will shoot out again afresh in the spring. Whoever, therefore, is desirous of securing his seedling-plants from this evil, should have his beds hooped, in order to throw mats over them during the hard frosts. Toward the latter end of March, or beginning of April, the plants having been in the seed-bed one or two years, they should be taken out, and planted in the nursery: The distance of one foot asunder, and two feet in the rows, should be given them. Hoeing the weeds down in the summer must also be allowed, as well as digging between the rows in the winter. Here they may stand until they are to be removed finally; but they must be gone over in the winter with the knife, and such irregular branches taken off

Cercopitheci
||
Cerealia.

as are produced near the root; by which management the tree may be trained up to a regular stem. Such, continues Hanbury, is the culture of the species of *cercis*; sorts that are not to be omitted where there are any pretensions to a collection. Besides, the wood itself is of great value; for it polishes exceedingly well, and is admirably veined with black and green.

CERCOPITHECI, in natural history, the name given by Mr Ray to monkeys, or the class of apes with long tails. See APE and SIMIA.

CERDA (John Lewis de la), a learned Jesuit of Toledo, wrote large commentaries on Virgil, which have been much esteemed; also several other works. He died in 1643, aged 80.

CERDONIANS, ancient heretics, who maintained most of the errors of Simon Magus, Saturninus, and the Manichees. They took their name from their leader *Cerdon*, a Syrian, who came to Rome in the time of pope Hyginus, and there abjured his errors: but in appearance only; for he was afterwards convicted of persisting in them, and accordingly cast out of the church again. *Cerdon* asserted two principles, the one good and the other evil: this last, according to him, was the creator of the world, and the god that appeared under the old law. The first, whom he called *unknown*, was the father of Jesus Christ; who, he taught, was incarnate only in appearance, and was not born of a virgin; nor did he suffer death but in appearance. He denied the resurrection; and rejected all the books of the Old Testament, as coming from an evil principle. Marcion, his disciple, succeeded him in his errors.

CEREALIA, in antiquity, feasts of Ceres, instituted by Triptolemus, son of Celeus king of Eleusine in Attica, in gratitude for his having been instructed by Ceres, who was supposed to have been his nurse, in the art of cultivating corn and making bread.

There were two feasts of this kind at Athens; the one called *Eleusinia*, the other *Thesmophoria*. See the article ELEUSINIA. What both agreed in, and was common to all the *cerealia*, was, that they were celebrated with a world of religion and purity; so that it was esteemed a great pollution to meddle, on those days, in conjugal matters. It was not Ceres alone that was honoured here, but also Bacchus. The victims offered were hogs, by reason of the waste they make in the products of the earth: whether there was any wine offered or not, is matter of much debate among the critics. Plautus and Macrobius seem to countenance the negative side; Cato and Virgil the positive. Macrobius says, indeed, they did not offer wine to Ceres, but *mulsum*, which was a composition of wine and honey boiled up together: that the sacrifice made on the 21st of December to that goddess and Hercules, was a pregnant sow, together with cakes and *mulsum*; and that this is what Virgil means by *Mili Baccbo*. The *cerealia* passed from the Greeks to the Romans, who held them for eight days successively; commencing, as generally held, on the fifth of the ides of April. It was the women alone who were concerned in the celebration, all dressed in white: the men, likewise in white, were only spectators. They eat nothing till after sun-set; in memory of Ceres, who in her search after her daughter took no repast but in the evening.

Nº 68.

After the battle of Cannæ, the desolation was so great at Rome, that there were no women to celebrate the feast, by reason they were all in mourning; so that it was omitted that year.

CEREALIA, in botany, from *Ceres* the goddess of corn; Linnæus's name for the larger esculent seeds of the grasses: these are rice, wheat, rye, barley, oats, millet, panic grass, Indian millet, holcus, zizania, and maize. To this head may be likewise referred darnel, (*lolium*); which, by preparation, is rendered esculent.

CEREBELLUM, the hinder part of the head. See ANATOMY, n° 133.

CEREBRUM, the BRAIN. Its structure and use are not so fully known as some other parts of the body, and different authors consider it in various manners. However, according to the observations of those most famed for their accuracy and dexterity in anatomical inquiries, its general structure is as given in ANATOMY, n° 132.

Dr Hunter observes, that the principal parts of the medullary substance of the brain in idiots and madmen, such as the *thalami nervorum opticorum*, and *medulla oblongata*, are found entirely changed from a medullary to a hard, tough, dark-coloured substance, sometimes resembling white leather.

CEREMONIAL (*ceremoniale*), a book in which is prescribed the order of the ceremonies to be observed in certain actions and occasions of solemnity and pomp. The ceremonial of the Roman church is called *ordo Romanus*. It was published in 1516 by the bishop of Corcyra; at which the college of cardinals were so scandalized, that some of them voted to have the author as well as book burnt, for his temerity in exposing the sacred ceremonies to the eyes of profane people.

CEREMONIAL is also used for the set or system of rules and ceremonies which custom has introduced for regulating our behaviour, and which persons practise towards each other, either out of duty, decency, or civility.

CEREMONIAL, in a more particular sense, denotes the manner in which princes and ambassadors use to receive and to treat one another. There are endless disputes among sovereigns about the *ceremonial*: some endeavouring to be on a level, and others to be superior; insomuch that numerous schemes have been proposed for settling them. The chief are, 1. to accommodate the difference by compromise or alternation, so that one shall precede now, the other the next time; or one in one place, and the other in another: 2. By seniority; so that an elder prince in years shall precede a younger, without any other distinction. These expedients, however, have not yet been accepted of by any, except some *alternate princes*, as they are called, in Germany.

CAREMONIAL is more particularly used in speaking of the laws and regulations given by Moses relating to the worship of God among the ancient Jews. In this sense it amounts to much the same with what is called the *Levitical law*, and stands contradistinguished from the moral as well as judicial law.

CEREMONY, an assemblage of several actions, forms, and circumstances, serving to render a thing more magnificent and solemn.

In 1646, M. Ponce published a history of ancient ceremonies, tracing the rise, growth, and introduction

Cerealia
||
Ceremony.

Master of
the Cere-
monies
||
Ceres.

of each rite into the church, and its gradual advancement to superstition therein. Many of them were borrowed from Judaism; but more seemingly from Paganism. Dr Middleton has given a fine discourse on the conformity between the pagan and popish ceremonies, which he exemplifies in the use of incense, holy water, lamps, and candles, before the shrines of saints, votive gifts or offerings round the shrines of the deceased, &c. In effect, the altars, images, crosses, processions, miracles, and legends; nay, even the very hierarchy, pontificate, religious orders, &c. of the present Romans, he shows, are all copied from their heathen ancestors.—We have an ample and magnificent account of the religious ceremonies and customs of all nations in the world, represented in figures designed by Picart, with historical explanations, and many curious dissertations.

Master of the CEREMONIES, an officer instituted by king James I. for the more honourable reception of ambassadors and strangers of quality. He wears about his neck a chain of gold, with a medal under the crown of Great Britain, having on one side an emblem of peace, with this motto, *Beati pacifici*; and on the other, an emblem of war, with *Dieu et mon droit*: his salary is 300*l. per annum*.

Assistant Master of the CEREMONIES, is to execute the employment in all points, whensoever the master of the ceremonies is absent. His salary is 141*l. 13s. and 4d. per annum*.

Marshall of the CEREMONIES is their officer, being subordinate to them both. His salary is 100*l. per annum*.

CERENZA, a town of Italy in the kingdom of Naples, and in the Hither Calabria, with a bishop's see. It is seated on a rock, in E. Long. 17. 5. N. Lat. 39. 23.

CERES, a Pagan deity, the inventor or goddess of corn; in like manner as Bacchus was of wine.

According to the poets, she was the daughter of Saturn and Ops, and the mother of Proserpine, whom she had by Jupiter. Pluto having stolen away Proserpine, Ceres travelled all over the world in quest of her daughter, by the help of a torch, which she had lighted in Mount Ætna.

As Ceres was thus travelling in search of her daughter, she came to Celeus king of Eleusis, and undertook to bring up his infant son Triptolemus. Being desirous to render her charge immortal, she fed him in the day-time with divine milk, and in the night covered him with fire. Celeus observing an unusual improvement in his son, resolved to watch his nurse, to which end he hid himself in that part of the house where she used to cover the child with fire; but when he saw her put the infant under the embers, he cried out and discovered himself. Ceres punished the curiosity and indiscretion of the father with death. Afterwards she taught the youth the art of sowing corn and other fruits, and mounted him in a chariot drawn by winged dragons, that he might traverse the world, and teach mankind the use of corn and fruits. After this, having discovered, by means of the nymph Arethusa, that Proserpine was in the infernal regions, she applied to Jupiter, and obtained of him that Proserpine should be restored, on condition that she had tasted nothing during her stay in that place but it being

discovered, by the information of Ascalaphus, that, as she was walking in Pluto's orchard, she had gathered an apple, and had tasted of some of the seeds, she was for ever forbidden to return. Ceres, out of revenge, turned Ascalaphus into an owl. At length, Jupiter, to mitigate her grief, permitted that Proserpine should pass one half of the year in the infernal regions with Pluto, and the other half with her mother on earth.

Cicero speaks of a temple of Ceres at Catanea in Sicily, where was a very ancient statue of that goddess, but entirely concealed from the sight of men, every thing being performed by matrons and virgins.

CERET, a town of France in Roussillon, with a magnificent bridge of a single arch. It is seated near the river Tec, in E. Long. 2. 46. N. Lat. 42. 23.

CEREUS, in botany. See CACTUS.

CERIGO, an island in the Archipelago, anciently called *Cythrea*; noted for being the birth-place of Helen, and, as the poets say, of Venus. At present, there is nothing very delightful in the place; for the country is mountainous, and the soil dry. It abounds in hares, quails, turtle, and excellent falcons. It is about 50 miles in circumference, and had formerly good towns; but there is now none remaining but that which gives name to the island. This is strong both by art and nature, it being seated on a craggy rock. The inhabitants are Christian Greeks, and subject to the Venetians, who keep a governor there, whom they change every two years.

CERINES, a town in the island of Cyprus, with a good castle, an harbour, and a bishop's see. E. Long. 33. 35. N. Lat. 35. 22.

CERINTHE, HONEYWORT: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 41st order, *Asperifolie*. The limb of the corolla is a ventricose tube with the throat pervious; and there are two bilocular seeds. There are three species, natives of Germany, Italy, and the Alps. They are low annual plants with purple, yellow, and red flowers, which may be propagated by seed sown in autumn, in a warm situation.

CERINTHIANS, ancient heretics, who denied the deity of Jesus Christ.—They took their name from Cerinthus, one of the first heresiarchs in the church, being cotemporary with St John. See CERINTHUS.

They believed that Jesus Christ was a mere man, born of Joseph and Mary; but that, in his baptism, a celestial virtue descended on him in form of a dove; by means whereof he was consecrated by the holy spirit, and made Christ. It was by means of this celestial virtue, therefore, that he wrought so many miracles; which, as he received it from heaven, quitted him after his passion, and returned to the place whence it came; so that Jesus, whom they called a *pure man*, really died and rose again; but that Christ, who was distinguished from Jesus, did not suffer at all. It was partly to refute this sect, that St John wrote his gospel. They received the gospel of St Matthew, to countenance their doctrine of circumcision, from Christ's being circumcised; but they omitted the genealogy. They discarded the epistles of St Paul, because that apostle held circumcision abolished.

CERINTHUS, a heresiarch, cotemporary with the apostles,

Ceret
||
Cerinthus.

Ceropegia,
Certhia.

apostles; ascribed the creation not to God, but to angels. He taught that Jesus Christ was the son of Joseph, and that circumcision ought to be retained under the gospel. He is looked upon as the head of the converted Jews, who raised in the church of Antioch the tumult of which St. Luke has given the history in the 15th chapter of the Acts. Some authors ascribe the book of the apocalypse to Cerinthus; adding, that he put it off under the name of St. John, the better to authorize his reveries touching Christ's reign upon earth: and it is even certain that he published some works of this kind under the title of *Apocalypse*. See APOCALYPSE.

CEROPEGIA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, *Contortæ*. There are two erect follicles; the seeds plumose or covered with a feathered pappus; the limb of the corolla connivent or closing at top.

Plate
CXV.

CERTHIA, in ornithology, the CREEPER or OX-EYE, a genus belonging to the order of picæ. The beak is arched, slender, sharp, and triangular; the tongue is sharp at the point; and the feet are of the walking kind, *i. e.* having the toes open and unconnected. Of this genus near 50 species have been enumerated by ornithologists; but Mr Latham supposes that many now described as species, will be found hereafter to be mere varieties; which, he adds, is no wonder, since many creepers do not gain their full plumage till the third year's moult. The following are a few of the most remarkable:

1. The familiaris, or common ox-eye, is grey above, and white underneath, with brown wings and ten white spots on the ten prime feathers. This bird is found in most parts of Europe, though it is believed no where so common as in Britain. It may be thought more scarce than it really is by the less attentive observer; for, supposing it on the body or branch of any tree, the moment it observes any one, it gets to the opposite side, and so on, let a person walk round the tree ever so often. The facility of its running on the bark of a tree, in all directions, is wonderful: This it does with as much ease as a fly on a glass window. Its food is principally, if not wholly, insects, which it finds in the chinks and among the moss of trees. It builds its nest in some hole of a tree, and lays generally five eggs, very rarely more than seven: these are ash-coloured, marked at the end with spots and streaks of a deeper colour; and the shell is observed to be pretty hard. It remains in the places which it frequents during the winter, and builds its nest early in the spring.

2. The hook-billed green creeper has a bill an inch and three quarters long, and bent quite in the shape of a semicircle; the plumage in general is olive green, palest beneath, and somewhat inclined to yellow: the quills and tail are dusky; the legs dusky brown; and the feathers just above the knee, or garter, white. It inhabits the Sandwich Islands in general, and is one of the birds whose plumage the natives make use of in constructing their feathered garments; which, having these olive-green feathers intermixed with the beautiful scarlet and yellow ones belonging to the next species, and yellow-tufted Bee-eater*, make some of the most beautiful coverings of these islanders.

reps.*

3. The hook-billed red creeper has the bill somewhat less hooked than the last species; the general colour of the plumage is scarlet; wings and tail black. In some birds the forehead is of a buff-colour; and the parts about the head and neck have both a mixture of buff and dusky black, which are suspected to be the birds not yet arrived at their full plumage.

4. The pusilla, or brown and white creeper, according to Edwards, is not above half the size of our European creeper. The upper part of the body is brown, with a changeable gloss of copper: the under parts are white; the quills brown, edged with glossy copper; the tail blackish, the outer feather tipped with white. The bird from which Edwards drew his figure had a label tied to it, by the name of Honey-thief. And that they are fond of honey is manifest, from those who keep birds at the Cape of Good Hope having many sorts in large cages, and supplying them with only honey and water; but besides this, they catch a great many flies, which come within the reach of their confinement; and these two make up their whole subsistence; indeed, it has been attempted to transport them further, but the want of flies on board a ship prevented them living more than three weeks; so necessary are insects to their subsistence.

5. The Loteni, or Loten's creeper, has the head, neck, back, rump, scapulars, and upper tail-coverts, of green gold: beneath, from the breast to the vent, of velvet black, which is separated from the green on the neck by a transverse bright violet band, a line and half in breadth: the lesser wing coverts are of this last colour; the middle coverts are green gold; and the greater coverts are very fine black, edged with green gold on the outer edge: the quills are of the same colour, as are also the tail feathers. The female differs in having the breast, belly, sides, thighs, under wing and tail coverts, of a dirty white, spotted with black; and the wings and tail not of so fine a black. It inhabits Ceylon, and Madagascar; and is called Angala-dian.

Buffon tells us, that it makes its nest of the down of plants, in form of a cup, like that of a chaffinch. the female laying generally five or six eggs; and that it is sometimes chased by a spider as large as itself, and very voracious, which seizes on the whole brood, and sucks the blood of the young birds.

6. The cœrulea, or blue creeper, has the head of a most elegant blue; but on each side there is a stripe of black like velvet, in which the eye is placed: the chin and throat are marked with black in the same manner; the rest of the body violet blue. It inhabits Cayenne. Seba says, that it makes its nest with great art. The outside is composed of dry stalks of grass, or such like; but within of very downy soft materials, in the shape of a retort, which it suspends from some weak twig, at the end of a branch of a tree; the opening or mouth downwards, facing the ground: the neck is a foot in length, but the real nest is quite at the top, so that the bird has to climb up this funnel-like opening to get at the nest. Thus it is secure from every harm; neither monkey, snake, nor lizard, daring to venture at the end of the branch, as it would not steadily support them.

7. The cardinal creeper, (*Lev. Mus.*), has the head, neck, and breast, of crimson colour; down the middle of

Certhia.

Certificate. of the back is a stripe of the same colour to the rump: the rest of the body is black; and the wings and tail are black. It inhabits the cultivated parts of the island of Tanna; is there called Kuyameta, and lives by sucking the nectar of flowers.

8. The mocking creeper is of the size of the lesser thrush. On the cheeks is a narrow white spot: the head, especially on the crown, is inclined to violet: the plumage in general is olive green, inclining to yellow on the under parts: the quills are brown; the secondaries edged with olive: the colour of the tail is like that of the secondaries, and somewhat forked: the legs are dusky blue, and the claws black. It inhabits both the islands of New Zealand. It has an agreeable note in general; but at times so varies and modulates the voice, that it seems to imitate the notes of all other birds; hence it was called by the English the Mocking-bird. This bird being fond of thrusting its head into the bosom of flowers which have a purplish-coloured farina, much of it adheres to the feathers about the head and bill, and in course gives the appearance above mentioned; but this in time rubs off, and the colour of the head appears the same with the rest of the plumage.

CERTIFICATE (*Trial by*), in the law of England, a species of trial allowed in such cases where the evidence of the person certifying is the only proper criterion of the point in dispute.* For when the fact in question lies out of the cognizance of the court, the judges must rely on the solemn averment or information of persons in such a station as affords them the most clear and competent knowledge of the truth. As therefore such evidence, if given to a jury, must have been conclusive, the law, to save trouble and circuitry, permits the fact to be determined upon such certificate merely. Thus, 1. If the issue be whether A was absent with the king in his army out of the realm in time of war, this shall be tried by the certificate of the marshal of the king's host in writing under his seal, which shall be sent to the justices. 2. If, in order to avoid an outlawry, or the like, it was alleged that the defendant was in prison, *ultra mare*, at Bourdeaux, or in the service of the mayor of Bourdeaux, this should have been tried by the certificate of the mayor; and the like of the captain of Calais. But when this was law, those towns were under the dominion of the crown of England. And therefore, by a parity of reason, it should now hold, that in similar cases arising at Jamaica or Minorca, the trial should be by certificate from the governor of those islands. We also find that the certificate of the queen's messenger, sent to summon home a peeress of the realm, was formerly held a sufficient trial of the contempt in refusing to obey such summons. 3. For matters within the realm; the customs of the city of London shall be tried by the certificate of the mayor and aldermen, certified by the mouth of their recorder; upon a surmise from the party alleging it, that the custom ought to be thus tried: else it must be tried by the country. As, the custom of distributing the effects of freemen deceased; of enrolling apprentices; or that he who is free of one trade may use another; if any of these, or other similar points come in issue. 4. The trial of all customs and practice of the courts shall be by certificate from the proper officers of those courts respectively;

*Blackst.
Comment.*

and what return was made on a writ by the sheriff or under-sheriff, shall be only tried by his own certificate.

CERTIORARI, in law, a writ which issues out of the chancery, directed to an inferior court, to call up the records of a cause there depending, in order that justice may be done. And this writ is obtained upon complaint, that the party who seeks it has received hard usage, or is not like to have an impartial trial in the inferior court. A certiorari is made returnable either in the king's bench, common pleas, or in chancery.

It is not only issued out of the court of chancery, but likewise out of the king's bench, in which last mentioned court it lies where the king would be certified of a record. Indictments from inferior courts, and proceedings of the quarter-sessions of the peace, may also be removed into the king's bench by a certiorari: and here the very record must be returned, and not a transcript of it; though usually in chancery, if a certiorari be returnable there, it removes only the tenor of the record.

CERTITUDE, considered in the things or ideas which are the objects of our understanding, is a necessary agreement or disagreement of one part of our knowledge with another: as applied to the mind, it is the perception of such agreement or disagreement; or such a firm well-grounded assent, as excludes not only all manner of doubt, but all conceivable possibility of a mistake.

There are three sorts of certitude, or assurance, according to the different natures and circumstances of things. 1. A physical or natural certitude, which depends upon the evidence of sense; as that I see such or such a colour, or hear such or such a sound; no body questions the truth of this, where the organs, the medium, and the object, are rightly disposed. 2. Mathematical certitude is that arising from mathematical evidence; such is, that the three angles of a triangle are equal to two right ones. 3. Moral certitude is that founded on moral evidence, and is frequently equivalent to a mathematical one; as that there was formerly such an emperor as Julius Cæsar, and that he wrote the commentaries which pass under his name; because the historians of these times have recorded it, and no man has ever disproved it since: this affords a moral certitude, in common sense so great, that one would be thought a fool or a madman for denying it.

CERTOSA, a celebrated Carthusian monastery, in the territory of the Pavese, in the duchy of Milan, four miles from Pavia; its park is surrounded with a wall 20 miles in circumference; but there are several small towns and villages therein.

CERVANTES. See **SAAVEDRA**.

CERVERA, a town of Spain, in Catalonia, seated on a small river of the same name, in E. Long. 1. 9. N. Lat. 41. 28.

CERVIA, a sea-port town of Italy, in Romagna, with a bishop's see, seated on the gulph of Venice, in E. Long. 13. 5. N. Lat. 44. 16.

CERVICAL NERVES, are seven pair of nerves, so called, as having their origin in the *cervix*, or neck.

CERVICAL Vessels, among anatomists, denote the arteries, veins, &c. which pass through the *veretæ* and muscles of the neck, up to the skull.

Cervix
||
Cervus.

CERVIX, in anatomy, properly denotes the hind part of the neck; as contradistinguished from the fore part, which is called *jugulum*, or the throat.

CERVIX of the *Scapula*, denotes the head of the shoulder-blade, or that upper process whose *sinus* receives the head of the *humerus*.

CERVIX of the *Uterus*, the neck of the *uterus*, or that oblong canal, or passage between the internal and external orifices, which receives and incloses the *penis* like a sheath, whence it is also called VAGINA.

CERUMEN, a thick, viscous, bitter, excrementitious humour, separated from the blood by proper glands placed in the *meatus auditorius*, or outer passage of the ear.

CERUSS, WHITE-LEAD, a sort of calx of lead, made by exposing plates of that metal to the vapour of vinegar. See CHEMISTRY-Index.

Ceruss, as a medicine, is used externally either mixed in ointments, or by sprinkling it on old gleetings and watery ulcers, and in many diseases of the skin. If, when it is reduced into a fine powder, it is received in with the breath in inspiration, and carried down into the lungs, it causes incurable asthma. Instances of the very pernicious effects of this metal are too often seen among those persons who work lead in any form, but particularly among the workers in white-lead.

The painters use it in great quantities; and that it may be afforded cheap to them, it is generally adulterated with common whiting.

CXXXI.

CERVUS, or DEER, in zoology, a genus of quadrupeds belonging to the order of Pecora. The horns are solid, brittle, covered with a hairy skin, and growing from the top; they likewise fall off and are renewed annually. There are eight fore-teeth in the under jaw, and they have no dog-teeth. The species of this genus enumerated by Linnæus are seven, viz.

1. The *Camelopardalis*, or Giraffe, with simple or unbranched horns, straight, about six inches long, covered with hair, and truncated at the end and tufted; in the forehead a tubercle, about two inches high, resembling a third horn. The fore legs are not much longer than the hind legs; but the shoulders are of a vast length, which gives the disproportionate height between the fore and hind parts: the head is like that of a stag: the neck is slender and elegant, and on the upper side is a short mane: the ears are large: tail is long, with strong hairs at the end: the colour of the whole animal a dirty white, marked with large broad rusty spots. This is an uncommon animal, few of them having been ever seen in Europe. It inhabits the forests of Ethiopia, and other interior parts of Africa, almost as high as Senegal; but is not found in Guinea, or any of the western parts; nor farther south than about lat. 28. 10. It is very timid, but not swift; and has been represented as living only by browsing the trees, being unable from the disproportionate length of its fore legs to graze or feed from the ground. When it would leap, it lifts up its fore legs and then its hind, like a horse whose fore legs are tied. It runs very badly and awkwardly, and is very easily taken. The latest and best description of this extraordinary quadruped is given in the 16th number of a work entitled, "A Description of the uncommon Animals and remarkable Productions in the Cabinet and Me-

nagerie of his Serene Highness the Prince of Orange;" by M. Vosmaer, Director of his Highness's Collections of Natural History. His account of the giraffe is composed partly from the notices of M. Vaillant and Mr Gordon of the Cape of Good Hope, and partly from his own observations on the skins of four of these animals, together with a complete skeleton, in the cabinet of curiosities under his care.

All the accounts we have of the giraffe, agree in representing its hind quarters as about $2\frac{1}{2}$ feet lower than its withers: but from observations made by the late professor Camper on the above mentioned skeleton, it would appear that naturalists have been greatly mistaken in this particular. That its fore legs are longer than its hind legs, is indeed true; but the difference is not more than seven inches, which, in a height of seven feet, is no great matter. It may, however (the professor observes), be rendered apparently more considerable by the obliquity of the thigh-bone with respect to the tibia, when compared with that of the humerus to the radius.

The giraffe has always been celebrated for the gentleness of its disposition. Antonius Constantius, a writer of the 15th century, in a letter to Galeas Manfredi, Prince of Faenza, dated Fano, 16th December 1486, gives an account of a giraffe which he saw there. He says it was so gentle, that it would eat bread, hay, or fruit, out of the hand of a child; and that, when led through the street, it would take whatever food of this kind was offered to it by the spectators at the windows, as it passed along. This character is confirmed by Mr Gordon, who relates, that a giraffe, which he had wounded, suffered him to approach it as it lay on the ground, without offering to strike with its horns, or showing any inclination to revenge itself: he even stroked it over its eyes several times, when it only closed them, without any signs of resentment. Its throat was afterwards cut for the sake of its skin; and when in the pangs of death, it struck the ground with its feet with a force much exceeding that of any other animal, and these seem to be its principal means of defence. M. Vosmaer observes, that both the male and female are furnished with horns, which, from their size and form, seem intended merely for ornament: they appear to be excrescences of the *os frontis*, and therefore are probably not deciduous. The notion of some writers, that the giraffe cannot feed from the ground, is confuted by the testimony of M. Vaillant, who asserts, that it can even drink from a river, the surface of which is lower than the bank on which it stands. M. Vosmaer observes, that this account is confirmed by considering the structure of the neck, the vertebrae of which are connected with those of the back by a very strong ligament.

The giraffe here described, which Mr Gordon, who dissected it, says was the largest he had ever seen, was 15 feet 4 inches Rhinland measure (about 15 feet 10 inches English) from the ground to the top of its head; the length of the body, from the chest to the rump, was 5 feet 7 inches Rhinland measure. M. Vaillant asserts, that he has seen several which were at least 17 feet high; and M. Vosmaer declares, that he has been assured by some very respectable inhabitants of the Cape, that they had seen and killed giraffes, which,

CERVUS.
Cameleopardalis.

Plate CXXIX.

A. Bell Pin. W. & S. Sculptor print.

Cervus.

which, including the horns, were 22 Rhinland feet in height.

The giraffe was known to the Romans in early times. It appears among the figures in the assemblage of eastern animals on the celebrated Prænentine Pavement, made by the direction of Sylla; and is represented both grazing and browsing, in its natural attitudes. It was exhibited at Rome by the popular Cæsar, among other animals in the Circæan games.

2. The Alces, Elk, or Moose Deer, has palmated horns, without any proper stem, and a fleshy protuberance on the throat. The neck is much shorter than the head, with a short, thick, upright mane, of a light brown colour. The eyes are small; the ears a foot long, very broad and slouching; nostrils very large; the upper lip square, hangs greatly over the lower, and has a deep sulcus in the middle, so as to appear almost bifid. This is the bulkiest animal of the deer kind, being sometimes 17 hands high, and weighing above 1200 pounds. The female is less than the male, and wants horns. The elks inhabit the isle of Cape Breton, Nova Scotia, and the western side of the bay of Fundy; Canada, and the country round the great lakes, almost as far south as the river Ohio. These are its present northern and southern limits. In all ages it affected the cold and woody regions in Europe, Asia, and America. They are found in all the woody tracts of the temperate parts of Russia, but not on the Arctic flats, nor yet in Kamtschatka. In Siberia they are of a monstrous size, particularly among the mountains. The elk and the moose, according to Mr Pennant, are the same species; the last derived from *musu*, which in the Algonkin language signifies that animal. The English used to call it the black moose, to distinguish it from the stag, which they named the grey moose. The French call it *Porignal*.

These animals reside amidst forests, for the convenience of browsing the boughs of trees, because they are prevented from grazing with any kind of ease, by reason of the shortness of their necks and length of their legs. They often have recourse to water-plants, which they can readily get at by wading. M. Sarrafin says, that they are very fond of the *anagris fœtida*, or stinking bean trefoil, and will uncover the snow with their feet in order to get at it. In passing through the woods, they raise their heads to a horizontal position, to prevent their horns from being entangled in the branches. They have a singular gait: their pace is a shambling trot; but they go with great swiftness. In their common walk they lift their feet very high, and will without any difficulty step over a gate five feet high. They feed principally in the night. If they graze, it is always against an ascent; an advantage they use for the reason above assigned. They ruminate like the ox. They go to rut in autumn; are at that time very furious, seeking the female by swimming from isle to isle. They bring two young at a birth, in the month of April, which follow the dam a whole year. During the summer they keep in families. In deep snows they collect in numbers in the forests of pines, for protection from the inclemency of the weather under the shelter of those evergreens. They are very inoffensive, except in the rut-

ting-season; or except they are wounded, when they will turn on the assailant, and attack him with their horns, or trample him to death beneath their great hoofs.

The flesh of the moose is extremely sweet and nourishing. The Indians say, that they can travel three times farther after a meal of moose, than after any other animal food. The tongues are excellent; but the nose is perfect marrow, and esteemed the greatest delicacy in Canada. The skin makes excellent buff; being strong, soft, and light. The Indians dress the hide, and, after soaking it for some time, stretch and render it supple by a lather of the brains in hot water. They not only make their snow-shoes of the skin, but after a chase form the canoes with it: they sew the skins neatly together, cover the seams with an unctuous earth, and embark in them with their spoils to return home. The hair on the neck, withers, and hams of a full-grown elk, is of much use in making mattresses and saddles; being by its great length well adapted for those purposes. The palmated parts of the horns are farther excavated by the savages, and converted into ladles, which will hold a pint.

It is not strange that so useful an animal should be a principal object of chase. The savages perform it in different ways. The first, and the more simple, is before the lakes or rivers are frozen. Multitudes assemble in their canoes, and form with them a vast crescent, each horn touching the shore. Another party perform their share of the chase among the woods; they surround an extensive tract, let loose their dogs, and press towards the water with loud cries. The animals, alarmed with the noise, fly before the hunters, and plunge into the lake, where they are killed by the persons in the canoes, prepared for their reception, with lances or clubs. The other method is more artful. The savages inclose a large space with stakes hedged with branches of trees, forming two sides of a triangle: the bottom opens into a second inclosure, completely triangular. At the opening are hung numbers of snares, made of slips of raw hides. The Indians, as before, assemble in great troops, and with all kinds of noises drive into the first inclosure not only the mooses, but the other species of deer which abound in that country: some, in forcing their way into the farthest triangle, are caught in the snares by the neck or horns; and those which escape the snares, and pass the little opening, find their fate from the arrows of the hunters, directed at them from all quarters. They are often killed with the gun. When they are first unharboured, they squat with their hind parts and make water, at which instant the sportsman fires; if he misses, the moose sets off in a most rapid trot, making, like the rein-deer, a prodigious rattling with its hoofs, and will run for 20 or 30 miles before it comes to bay or takes the water. But the usual time for this diversion is the winter. The hunters avoid entering on the chase till the sun is strong enough to melt the frozen crust with which the snow is covered, otherwise the animal can run over the firm surface: they wait till it becomes soft enough to impede the flight of the moose; which sinks up to the shoulders, flounders, and gets on with great difficulty. The sportsman pursues at his ease on his broad rackets, or snow-

Cervus.

Cervus. snow-shoes, and makes a ready prey of the distressed animals.

As weak against the mountain heaps they push
Their beating breast in vain, and piteous bray,
He lays them quivering on th' ensanguin'd snows,
And with loud shouts rejoicing bears them home.

THOMPSON.

The opinion of this animal's being subject to the epilepsy seems to have been universal, as well as the cure it finds by scratching its ear with the hind hoof till it draws blood. That hoof has been used in Indian medicine for the falling-sickness; they apply it to the heart of the afflicted, make him hold it in his left hand, and rub his ear with it. They use it also in the colic, pleurisy, vertigo, and purple fever; pulverising the hoof, and drinking it in water. The Algonkins pretend that the flesh imparts the disease; but it is notorious that the hunters in a manner live on it with impunity. The savages esteem the moose a beast of good omen; and are persuaded that those who dream often of it may flatter themselves with long life.

The elk was known to the Romans by the name of *Alce* and *Macblis*: they believed that it had no joints in its legs; and, from the great size of the upper lip, imagined it could not feed without going backward as it grazed.

3. The *Elaphus*, or Stag, with long cylindrical ramified horns bent backwards, and slender sharp brow antlers. The colour is generally a reddish brown with some black about the face, and a black list down the hind part of the neck and between the shoulders. Stags are common to Europe, Barbary, the north of Asia, and America. In spring, they shed their horns, which fall off spontaneously, or by rubbing them gently against the branches of trees. It is seldom that both horns fall off at the same time, the one generally preceding the other a day or two. The old stags cast their horns first, which happens about the end of February or beginning of March. An aged stag, or one in his seventh year or upwards, does not cast his horns before the middle of March; a stag of six years sheds his horns in April; young stags, or those from three to five years old, shed their horns in the beginning, and those which are in their second year, not till the middle or end of May. But in all this there is much variety; for old stags sometimes cast their horns sooner than those which are younger. Besides, the shedding of the horns is advanced by a mild, and retarded by a severe and long winter.

As soon as the stags cast their horns, they separate from each other, the young ones only keeping together. They no longer haunt the deepest recesses of the forest, but advance into the cultivated country, and remain among brushwood during the summer, till their horns are renewed. In this season, they walk with their heads low to prevent their horns from rubbing against the branches; for they continue to have sensibility till they acquire their full growth. The horns of the oldest stags are not half completed in the middle of May, and acquire their full length and hardness before the end of July. Those of the younger stags are proportionally later both in shedding and being renewed. But as soon as they have acquired their full dimensions and solidity, the stags rub them

against the trees, in order to clear them of a skin with which they are covered.

Soon after the stags have polished their horns, they begin to feel the impressions of love. Towards the end of August or beginning of September, they leave the coppice, return to the forests, and search for the hinds. They cry with a loud voice; their neck and throat swell; they become perfectly restless, and traverse in open day the fields and the fallow grounds; they strike their horns against trees and hedges; in a word, they seem to be transported with fury, and run from country to country till they find the hinds or females, whom they pursue and compel into compliance; for the female at first avoids and flies from the male, and never submits to his embraces till she be fatigued with the pursuit. The old hinds likewise come in season before the younger ones. When two stags approach the same hind, they must fight before they enjoy. If nearly equal in strength, they threaten, paw the ground, set up terrible cries, and attack each other with such fury, that they often inflict mortal wounds with the strokes of their horns. The combat never terminates but in the defeat or flight of one of the rivals. The conqueror loses not a moment in enjoying his victory, unless another rival approaches, whom he is again obliged to attack and repel. The oldest stags are always masters of the field; because they are stronger and more furious than the young ones, who must wait patiently till their superiors tire, and quit their mistresses. Sometimes, however, the young stags accomplish their purposes when the old ones are fighting, and, after a hasty gratification, fly off. The hinds prefer the old stags, not because they are most courageous, but because they are much more ardent. They are likewise more inconstant, having often several females at a time; and when a stag has but one hind, his attachment to her does not continue above a few days: He then leaves her, goes in quest of another, with whom he remains a still shorter time; and in this manner passes from one to another till he is perfectly exhausted.

This ardour of love lasts only three weeks, during which the stags take very little food, and neither sleep nor rest. Night and day, they are either walking, running, fighting, or enjoying the hinds. Hence, at the end of the rutting season, they are so meagre and exhausted, that they recover not their strength for a considerable time. They generally retire to the borders of the forests, feed upon the cultivated fields, where they find plenty of nourishment, and remain there till their strength is re-established. The rutting season of old stags commences about the beginning, and ends about the 20th day of September. In those of six or seven years old, it begins about the 10th of September, and concludes in the beginning of October. In young stags, or those in their third, fourth, or fifth year, it begins about the 20th of September, and terminates about the 15th of October; and at the end of October, the rutting is all over, excepting among the *prickets*, or those which have entered into their second year; because they, like the young hinds, are latest of coming into season. Hence, at the beginning of November, the season of love is entirely finished; and the stags, during this period of weakness and lassitude, are easily hunted down. In seasons when acorns and

Cervus.

and other nuts are plentiful, the stags soon recover their strength, and a second rutting frequently happens at the end of October; but it is of much shorter duration than the first.

In climates warmer than that of France, the rutting time, like the seasons, is more forward. Aristotle informs us, that, in Greece, it commences in the beginning of August, and terminates about the end of September. The hinds go with young eight months and some days, and seldom produce more than one fawn. They bring forth in May or the beginning of June, and so anxiously conceal their fawns, that they often expose themselves to be chased, with a view to draw off the dogs, and afterwards return to take care of their young. All hinds are not fertile; for some of them never conceive. These barren hinds are grosser and fatter than those which are prolific, and also come soonest in season. The young are not called *fawns* or *calves* after the sixth month: The knobs of their horns then begin to appear, and they take the name of *knobbers* till their horns lengthen into *spears*, and then they are called *brocks* or *staggards*. During the first season, they never leave their mothers. In winter, the stags and hinds, of all ages, keep together in flocks, which are always more numerous in proportion to the rigour of the season. They separate in spring: The hinds retire to bring forth; and, during this period, the flocks consist only of knobbers and young stags. In general, the stags are inclined to associate, and nothing but fear or necessity obliges them to disperse.

The life of the stag is spent in alternate plenty and want, vigour and debility, health and sickness, without having any change introduced into his constitution by these opposite extremes. He lives as long as other animals which are not subjected to such vicissitudes. As he grows five or six years, he lives seven times that number, or from 35 to 40 years. What has been reported concerning the longevity of the stag merits no credit. It is only a popular prejudice which prevailed in the days of Aristotle, and which that philosopher considered as improbable, because neither the time of gestation, nor of the growth of the young stag, indicated long life. This authority ought to have abolished the prejudice; but it has been renewed, in the ages of ignorance, by a fabulous account of a stag taken by Charles VI. in the forest of Senlis, with a collar upon which was written this inscription, *Cæsar hoc me donavit*. The love of the marvellous inclined men to believe that this animal had lived 1000 years, and had his collar from a Roman emperor, rather than to suppose that he came from Germany, where all the emperors take the name of *Cæsar*.

The stag appears to have a fine eye, an acute smell, and an excellent ear. When listening, he raises his head, erects his ears, and hears from a great distance. When he is going into a coppice, or other half covered place, he stops to look round him on all sides, and scents the wind, to discover if any object is near that might disturb him. He is a simple, and yet a curious and crafty animal. When hissed or called to from a distance, he stops short, and looks steadfastly, and with a kind of admiration, at carriages, cattle, or men; and if they have neither arms nor dogs, he moves on unconcernedly, and without flying. He appears to listen, with great tranquillity and delight, to the shepherd's pipe; and the hunters sometimes employ this

artifice to encourage and deceive him. In general, he is less afraid of men than of dogs, and is never suspicious, or uses any arts of concealment, but in proportion to the disturbances he has received. He eats slow, and has a choice in his aliment; and after his stomach is full, he lies down, and ruminates at leisure. He seems to ruminate with less facility than the ox. It is only by violent shakes that the stag can make the food rise from his first stomach. This difficulty proceeds from the length and direction of the passage through which the aliment has to go. The neck of the ox is short and straight, but that of the stag is long and arched; and therefore greater efforts are necessary to raise the food. These efforts are made by a kind of hiccup, the movement of which is apparent, and continues during the time of rumination. His voice is stronger, and more quivering, in proportion as he advances in years. The voice of the hind is shorter and more feeble. She never bellows from love, but from fear. The stag, during the rutting season, bellows in a frightful manner: He is then so transported, that nothing disturbs or terrifies him. He is therefore easily surprised; as he is loaded with fat, he cannot keep long before the dogs. But he is dangerous when at bay, and attacks the dogs with a species of fury. He drinks none in winter nor in spring, the dews and tender herbage being then sufficient to extinguish his thirst; but, during the parching heats of summer, to obtain drink, he frequents the brooks, the marshes, and the fountains; and in the season of love, he is so over-heated, that he searches every where for water, not only to satisfy his immoderate thirst, but to bathe and refresh his body. He then swims easier than at any other times on account of his fatness. He has been observed crossing very large rivers. It has even been alleged, that, attracted by the odour of the hinds, the stags, in the rutting season, throw themselves into the sea, and pass from one island to another at the distance of several leagues. They leap still more nimbly than they swim; for, when pursued, they easily clear a hedge or a pale fence of six feet high. Their food varies in different seasons. In autumn, after rutting, they search for the buds of green shrubs, the flowers of broom or heath, the leaves of brambles, &c. During the snows of winter, they feed upon the bark, moss, &c. of trees; and in mild weather, they browse in the wheat-fields. In the beginning of spring, they go in quest of the catkins of the trembling poplar, willow, and hazel-trees, the flowers and buds of the cornel tree, &c. In summer, when they have great choice, they prefer rye to all other grain, and the black berry-bearing alder to all other wood. The flesh of the fawn is very good: that of the hind and knobber not absolutely bad; but that of the stag has always a strong and disagreeable taste. The skin and the horns are the most useful parts of this animal. The skin makes a pliable and very durable leather. The horns are used by cutlers, sword-slippers, &c. and a volatile spirit, much employed in medicine, is extracted from them by the chymists.

In America, stags feed eagerly on the broad-leaved kalmia; yet that plant is a poison to all other horned animals: their intestines are found filled with it during winter. If their entrails are given to dogs, they become stupified, and as if drunk, and often are so ill

Cervus.

Cervus.

as hardly to escape with life. The American stags grow very fat: their tallow is much esteemed for making of candles. The Indians shoot them. As they are very shy animals, the natives cover themselves with a hide, leaving the horns erect; under shelter of which they walk within reach of the herd. De Brie, in the 25th plate of the History of Florida, gives a very curious representation of this artful method of chase, when it was visited by the French in 1564. Their skins are an article of commerce imported by the Hudson's Bay company; but brought from the distant parts far inland by the Indians, who bring them from the neighbourhood of the lakes. In most parts of North America they are called the grey moose, and the elk; this has given occasion to the mistaken notion of that great animal being found in Virginia and other southern provinces.

In Britain the stag is become less common than formerly; its excessive viciousness during the rutting season, and the badness of its flesh, induce most people to part with the species. Stags are still found wild in the Highlands of Scotland, in herds of four or five hundred together, ranging at full liberty over the vast hills of the north. Formerly the great Highland chieftains used to hunt with the magnificence of an eastern monarch, assembling four or five thousand of their clan, who drove the deer into the toils or to the stations the lairds had placed themselves in: but as this pretence was frequently used to collect their vassals for rebellious purposes, an act was passed prohibiting any assemblies of this nature. Stags are likewise met with on the moors that border on Cornwall and Devonshire; and in Ireland on the mountains of Kerry, where they add greatly to the magnificence of the romantic scenery to the lake of Killarney. The stags of Ireland during its uncultivated state, and while it remained an almost boundless tract of forest, had an exact agreement in habit with those that range at present through the wilds of America. They were less in body, but very fat; and their horns of a size far superior to those of Europe, but in form agreed in all points.

The chase of the stag has been formed into an art, and requires a species of knowledge which can only be learned by experience: It implies a royal assemblage of men, horses, and dogs, all so trained, practised, and disciplined, that their movements, their researches, and their skill, must concur in producing one common end. The huntsman should know the age and the sex of the animal; he should be able to distinguish with precision, whether the stag he has harboured with his hound be a knobber, a young stag, in his sixth or seventh year, or an old stag. The chief marks which convey this intelligence is derived from the foot, and the excrement. The foot of the stag is better formed than that of the hind, or female. Her leg is more gross and nearer the heel. The impressions of his feet are rounder, and farther removed from each other. He moves more regularly, and brings the hind foot into the impression made by the fore-foot. But the distance between the steps of the hind are shorter, and her hind-feet strike not so regularly the track of the fore feet. As soon as the stag acquires his fourth horns, he is easily distinguished; but to know the foot of a young stag from that of a hind, requires re-

N^o 68.

peated experience. Stags of six, seven, &c. years, are still more easily known; for their fore-foot is much larger than the hind-foot; the older they are, the sides of their feet are the more worn; the distance of their steps are more regular than those of young stags; they always place their hind-foot exactly in the track of the fore-foot, excepting, when they shed their horns, the old stags misplace, at this season, nearly as often as the young ones; but in this they are more regular than the hind or young stag, placing the hind-foot always at the side of the fore-foot, and never beyond or within it. When the huntsman, from the dryness of the season, or other circumstances, cannot judge by the foot, he is obliged to trace the animal backwards, and endeavour to find his dung. This mark requires, perhaps, greater experience than the knowledge of the foot; but without it the huntsman would be unable to give a proper report to the company. After the report of the huntsman, and the dogs are led to the refuge of the stag, he ought to encourage his hound, and make him rest upon the track of the stag, till the animal be unharboured. Instantly the alarm is given to uncouple the dogs, which ought to be enlivened by the voice and the horn of the huntsman. He should also diligently observe the foot of the stag, in order to discover whether the animal has started, and substituted another in his place. But it is then the business of the hunters to separate also, and to recal the dogs which have gone astray after false game. The huntsman should always accompany his dogs, and encourage, without pressing them too hard. He should assist them in detecting all the arts of escape used by the stag; for this animal has remarkable address in deceiving the dogs. With this view, he often returns twice or thrice upon his former steps; he endeavours to raise hinds or younger stags to accompany him, and draw off the dogs from the object of their pursuit; he then flies with redoubled speed, or springs off at side, lies down on his belly, and conceals himself. In this case, when the dogs have lost his foot, the huntsmen, by going backwards and forwards, assist them in recovering it. But if they cannot find it, they suppose that he is resting within the circuit they have made, and go in quest of him. But if they are still unable to discover him, there is no other method left, but, from viewing the country, to conjecture where he may have taken refuge, and repair to the place. As soon as they have recovered his foot, and put the dogs upon the track, they pursue with more advantage, because they perceive that the stag is fatigued. Their ardour augments in proportion to his feebleness; and their scent becomes more distinct as the animal grows warm. Hence they redouble their cries and their speed; and though the stag practises still more arts of escape than formerly, as his swiftness is diminished, his arts and doublings become gradually less effectual. He has now no other resource but to fly from the earth which he treads, and get into the waters, in order to cut off the scent from the dogs. The huntsmen go round these waters, and again put the dogs on the track of his foot. The stag, after taking to the water, is incapable of running far, and is soon at bay. But he still attempts to defend his life, and often wounds the dogs, and even the huntsmen when too forward, by blows with his horns, till one of them cuts his

hams to make him fall, and then puts an end to his life by a blow of a hanger. They now celebrate the death of the stag by a flourish of their horns; the dogs are allowed to trample upon him, and at last partake richly of the victory by devouring his flesh.

4. The Tarandus, or Rein-deer, is a native of Lapland, and the northern parts of Europe, Asia, and America. The horns are large, cylindrical, branched, and palmated at the tops. Two of the branches hang over the face. He is about the size of a buck, of a dirty whitish colour; the hairs of his skin are thick and strong. To the Laplanders this animal is the substitute of the horse, the cow, the goat, and the sheep; and is their only wealth: the milk affords them cheese; the flesh, food; the skin, cloathing; the tendons, bow-strings; and when split, thread; the horns, glue; the bones, spoons. During the winter it supplies the want of a horse, and draws their sledges with amazing swiftness over the frozen lakes and rivers, or over the snow, which at that time covers the whole country. A rich Laplander is possessed of a herd of 1000 rein deer. In autumn they seek the highest hills, to avoid the Lapland gad-fly, which at that time deposits its eggs in their skin; it is the pest of these animals, and numbers die that are thus visited. The moment a single fly appears, the whole herd instantly perceives it; they fling up their heads, toss about their horns, and at once attempt to fly for shelter amidst the snows of the loftiest Alps. In summer they feed on several plants; but during winter on the rein-liverwort, which lies far beneath the snow, which they remove with their feet and palmated brow antlers, in order to get at their beloved food.

The Samoieds, less intelligent than the Laplanders, consider them in no other view than as animals of draught, to convey them to the chase of the wild reins; which they kill for the sake of the skins, either to clothe themselves, or to cover their tents. They know not the cleanly delicacy of the milk or cheese; but prefer for their repast the intestines of beasts, or the half-putrid flesh of a horse, ox, or sheep, which they find dead on the high road.—The Koreki, a nation of Kamtschatka, may be placed on a level with the Samoieds. They keep immense herds of reins; some of the richest to the amount of 10 or 20 thousand; yet so sordid are they as to eat none except such as they kill for the sake of the skins; an article of commerce with their neighbours the Kamtschatkans; otherwise they content themselves with the flesh of those which die by disease or chance. They train them in the sledge, but neglect them for every domestic purpose. Their historian says, they couple two to each carriage; and that the deer will travel 150 versts in a day, that is, 112 English miles. They castrate the males by piercing the spermatic arteries, and tying the scrotum tight with a thong.—The savage and uninformed Eskimaux and Greenlanders, who possess, amidst their snows, these beautiful animals, neglect not only the domestic uses, but even are ignorant of their advantage in the sledge. Their element is properly the water; their game the seals. They seem to want powers to domesticate any animals except dogs. They are at enmity with all; consider them as an object of chase, and of no utility till deprived of life. The flesh of the rein is the most coveted part of their food; they eat it

VOL. IV. PART I.

raw, dressed, and dried and smoked with the snow lichen. The wearied hunters will drink the raw blood; but it is usually dressed with the berries of the heath: they eagerly devour the contents of the stomach, but use the intestines boiled. They are very fond of the fat, and will not lose the least bit. The skin, sometimes a part of their cloathing, dressed with the hair on, is soft and pliant; it forms also the inner lining of their tents, and most excellent blankets. The tendons are their bow-strings, and when split are the threads with which they sew their jackets.

The Greenlanders, before they acquired the knowledge of the gun, caught them by what was called the *clapper-hunt*. The women and children surrounded a large space, and, where people were wanting, set up poles capped with a turf in certain intervals, to terrify the animals; they then with great noise drove the reins into the narrow defiles, where the men lay in wait and killed them with harpoons or darts. But they are now become very scarce.

The rein-deers are found in the neighbourhood of Hudson's Bay, in most amazing numbers, columns of eight or ten thousand are seen annually passing from north to south in the months of March and April, driven out of the woods by the musketoos, seeking refreshment on the shore, and a quiet place to drop their young. They go to rut in September, and the males soon after shed their horns; they are at that season very fat, but so rank and musky as not to be eatable. The females drop their young in June, in the most sequestered spots they can find; and then they likewise lose their horns. Beasts of prey follow the herds: first, the wolves, who single out the stragglers (for they fear to attack the drove), detach and hunt them down: the foxes attend at a distance, to pick up the offals left by the former. In autumn the deer with the fawns remigrate northward. The Indians are very attentive to their motions; for the rein forms the chief part not only of their dress but of their food. They often kill multitudes for the sake of their tongues only; but generally they separate the flesh from the bones, and preserve it by drying it in the smoke; they also save the fat, and sell it to the English in bladders, who use it in frying instead of butter. The skins are also an article of commerce, and used in London by the Breeches-makers. The Indians shoot them in the winter. The English make hedges with stakes and boughs of trees along the woods for five miles in length, leaving openings at proper intervals beset with snares, in which multitudes are taken. The Indians also kill great numbers during the seasons of migration, watching in their canoes, and spearing them while passing over the rivers of the country, or from island to island; for they swim most admirably well.

5. The Dama or Fallow-deer, Buck and Doe; with horns branched, compressed, and palmated at the top. The colour is various; reddish, deep brown, white or spotted. This species is not so universal as the stag: rare in France and Germany. It is found in Greece, the Holy Land, and the north of China. They are very numerous in England; but, except on a few chases, confined in parks. None originally in America. They are easily tamed; and their flesh, which goes by the name of venison, is in high esteem among the luxurious. During rutting-time they will contend

Q q

with

Cervus.

Cervus. with each other for their mistress, but are less fierce than the stag; during that season, the male will form a hole in the ground, make the female lie down in it, and then often walk round and smell at her. Moore speaks of a species found on the banks of the Gambia, in the interior parts of Africa, near Barracunda, called *Toncong*, which he says differed not in form from the English fallow-deer; only that its size was equal to that of a small horse, and weighed 300 lb. It had also on its neck an erect black mane, four or five inches long.—Mr White, in his Natural History of Pelborn, mentions, as a piece of information to naturalists, that if some curious gentleman would procure the head of a fallow deer, and have it dissected, he would find it furnished with two *spiracula*, or breathing-places, besides the nostrils; probably analogous to the *puncta lachrymalia* in the human head. When deer are thirsty they plunge their noses, like some horses, very deep under water, while in the act of drinking, and continue them in that situation for a considerable time; but, to obviate any inconveniency, they can open two vents, one at the inner corner of each eye, having a communication with the nose. This seems, as our author observes, to be an extraordinary provision of nature; for it looks as if these creatures could not be suffocated, though their mouths and nostrils were both stopped. This curious formation of the head, he farther remarks, may be of singular service to beasts of chase, by affording them free respiration; and no doubt these additional nostrils are thrown open when they are hard run. Mr Pennant has observed the same curious organization in the antelope. See CAPRA.

6. The Capreolus, or Roe-buck, has erect, cylindrical, branched horns, and forked at the top. His size is only three feet nine inches long, two feet three inches high before, and two feet seven inches high behind: weight from 50 to 60 lb. Though the least of the deer-kind, his figure is most elegant and handsome. His eyes are more brilliant and animated than those of the stag. His limbs are more nimble, his movements quicker, and he bounds, seemingly without effort, with equal vigour and agility. His coat, or hair, is always clean, smooth, and glossy. He never wallows in the mire like the stag. He delights in dry and elevated situations, where the air is purest. He is likewise more crafty, conceals himself with greater address, is more difficult to trace, and derives superior resources from instinct: for though he has the misfortune to leave behind him a stronger scent than the stag, which redoubles the ardour and appetite of the dogs, he knows how to withdraw himself from their pursuit, by the rapidity with which he begins his flight, and by his numerous doublings. He delays not his arts of defence till his strength fails him; but, as soon as he finds that the first efforts of a rapid chase have been unsuccessful, he repeatedly returns on his former steps; and after confounding, by these opposite movements, the direction he has taken, after intermixing the present with the past emanations from his body, he rises from the earth by a great bound, and, retiring to a side, he lies down flat on his belly; and in this immoveable situation, he allows the whole troop of his deceived enemies to pass very near him.

The roe-deer differs from the stag and fallow-deer

in disposition, temperament, manners, and almost every natural habit. Instead of associating in herds, they live in separate families. The father, mother, and young, go together, and never mix with strangers. They are constant in their amours, and never unfaithful like the stag. As the females generally produce two fawns, the one male and the other female, these young animals, brought up and nourished together, acquire so strong a mutual affection, that they never quit each other, unless one of them meets with a misfortune, which never ought to separate lovers. This attachment is more than love; for though always together, they feel the ardour of the rut but once a year, and it continues only fifteen days, commencing at the end of October, and ending before the fifteenth day of November. They are not then, like the stag, overloaded with fat: they have no strong smell, no fury, in a word, nothing that can change the state of their bodies. During this period, they indeed suffer not their fawns to remain with them. The father drives them off, as if he meant to oblige them to yield their place to those which are to succeed, and to form new families for themselves. However, after the rutting season is past, the fawns return to their mother, and remain with her some time; after which they separate for ever, and remove to a distance from the place which gave them birth.

The female goes with young five months and a half, and brings forth about the end of April or beginning of May. She produces two at a time, which she is obliged to conceal from the buck while very young. In 10 or 12 days they acquire strength sufficient to enable them to follow her. When threatened with danger, she hides them in a close thicket, and, to preserve them, presents herself to be chased. But notwithstanding all her care and anxiety, the young are sometimes carried off by men, dogs, or wolves.

Roe-bucks prefer a mountainous woody country to a plain one. They were formerly very common in Wales, in the north of England; and in Scotland; but at present the species nowhere exists in Great Britain except in the Scottish highlands. In France they are more frequent; they are also found in Italy, Sweden, and Norway; and in Asia they are met with in Siberia. The first that are met with in Great Britain are in the woods on the south side of Loch-Rannoch, in Perthshire: the last in those of Longwal, on the southern borders of Caithness; but they are most numerous in the beautiful forests of Invercauld, in the midst of the Grampian hills. They are unknown in Ireland. Wild roes, during summer, feed on grass; and are very fond of the *rubus saxatilis*, called in the Highlands the roe-buck berry; but in the winter time, when the ground is covered with snow, they browse on the tender branches of the fir and birch.

7. The Guineensis, about the size of a cat, is of a grayish colour, and black underneath. It is a native of Guinea, and the size and figure of its horns have not been hitherto described with any precision.

8. The Axis, or Speckled Deer, has slender trifurcated horns; the first branch near the base, the second near the top, each pointing upwards. This species is about the size of the fallow-deer; of a light red colour; the body beautifully marked with white spots; along

Cervus. along the lower part of the sides, next the belly, is a line of white: the tail long, as that of a fallow-deer; red above, white beneath.—They are common on the banks of the Ganges, and in the isle of Ceylon. Pliny describes them well among the animals of India, and adds that they were sacred to Bacchus. They will bear our climate; and have bred in the prince of Orange's menagerie near the Hague. They are very tame, and have the sense of smelling in an exquisite degree. They readily eat bread, but will refuse a piece that has been breathed on: many other animals of this, the antelope and goat kind, will do the same.

9. The Porcine or Hog Deer, has slender trifurcated horns, 13 inches long: His body is thick and clumsy; his legs are fine and slender: The upper part of the neck, body, and sides, are brown; belly and rump, of a lighter colour.—They are found in Bengal; and called, from the thickness of their body, *hog-deer*. The same species is also found in Borneo. They are taken in square pit-falls, about four feet deep, covered with some slight materials. Of their feet, as well as those of the lesser species of musks and antelopes, are made tobacco-stoppers.

10. The Virginiana, or Virginian Deer, has slender horns, bending very much forward; numerous branches on the interior sides; no brow antlers. It is about the size of the English fallow-deer; of a light colour, cinereous brown. A quite distinct species, and peculiar to America. It inhabits all the provinces south of Canada, but in greatest abundance in the southern; but especially the vast savannas contiguous to the Mississippi, and the great rivers which flow into it. They graze in herds innumerable, along with the stags and buffaloes. This species probably extends to Guiana, and is the *baieu* of that country, which is said to be about the size of a European buck, with short horns, bending at their ends. They are capable of being made tame; and when properly trained, are used by the Indians to decoy the wild deer (especially in the rutting season) within shot. Both bucks and does herd from September to March; after that they separate, and the does secrete themselves to bring forth, and are found with difficulty. The bucks from this time keep separate till the amorous season of September revolves. The deer begin to feed as soon as night begins; and sometimes, in the rainy season, in the day; otherwise they seldom or never quit their haunts. An old American sportsman has remarked, that the bucks will keep in the thickets for a year, or even two.

These animals are very restless, and always in motion, coming and going continually. Those which live near the shores are lean and bad, subject to worms in their heads and throats, generated from the eggs deposited in those parts. Those that frequent the hills and savannas are in better case, but the venison is dry. In hard winters they will feed on the long moss which hangs from the trees in the northern parts.

These and other cloven-footed quadrupeds of America are very fond of salt, and resort eagerly to the places impregnated with it. They are always seen in great numbers in the spots where the ground has been torn by torrents or other accidents, where they are seen licking the earth. Such spots are called *licking-places*.

The hunters are sure of finding the game there; for notwithstanding they are often disturbed, the buffaloes and deer are so passionately fond of the savoury regale, as to bid defiance to all danger, and return in droves to these favourite haunts.

The deer are of the first importance to the savages. The skins form the greatest branch of their traffick, by which they procure from the colonists, by way of exchange, many of the articles of life. To all of them the flesh is the principal food throughout the year; for drying it over a gentle but clear fire, after cutting it into small pieces, it is not only capable of long preservation, but is very portable in their sudden excursions, especially when reduced to powder, which is frequently done.

Hunting is more than an amusement to these people. They give themselves up to it not only for the sake of subsistence, but to fit themselves for war, by habituating themselves to fatigue. A good huntsman is an able warrior. Those who fail in the sports of the field are never supposed to be capable of supporting the hardships of a campaign; they are degraded to ignoble offices, such as dressing the skins of deer, and other employs allotted only to slaves and women. When a large party meditates a hunting-match, which is usually at the beginning of winter, they agree on a place of rendezvous, often 500 miles distant from their homes, and a place perhaps that many of them had never been at. They have no other method of fixing on the spot than by pointing with their finger. The preference is given to the eldest, as the most experienced. When this matter is settled, they separate into small parties, travel and hunt for subsistence all the day, and rest at night; but the women have no certain resting-places. The savages have their particular hunting countries; but if they invade the limits of those belonging to other nations, feuds ensue, fatal as those between Percy and Douglas in the famed Chevy Chase. As soon as they arrive on the borders of the hunting country (which they never fail doing to a man, be their respective routes ever so distant or so various), the captain of the band delineates on the bark of a tree his own figure, with a rattlesnake twined round him with distended mouth; and in his hand a bloody tomahawk. By this he implies a destructive menace to any who are bold enough to invade their territories, or to interrupt their diversion.—The chase is carried on in different ways. Some surprise the deer by using the stake of the head, horns, and hide; but the general method is performed by the whole body. Several hundreds disperse in a line, encompassing a vast space of country, fire the woods, and drive the animals into some strait or peninsula, where they become an easy prey. The deer alone are not the object; foxes, raccoons, bears, and all beasts of fur, are thought worthy of attention, and form articles of commerce with the Europeans.

The number of deer destroyed in some parts of America is incredible; as is pretended, from an absurd idea which the savages have, that the more they destroy, the more they shall find in succeeding years. Certain it is that multitudes are destroyed; the tongues only preserved, and the carcases left a prey to wild beasts. But the motive is much more political. The

Cervus
||
Cession.

savages well discern, that should they overstock the market, they would certainly be over-reached by the European dealers, who take care never to produce more goods than are barely sufficient for the demand of the season, establishing their prices according to the quantity of furs brought by the natives.

CERVUS Volans, in natural history, a name given by authors to the stag-fly, or horned beetle, a very large species of beetle with horns sloped, and something like those of the stag.

CERYX, in antiquity. The ceryces were a sort of public criers appointed to proclaim or publish things aloud in assemblies. The *ceryx* among the Greeks answered to the *præco* among the Romans. Our criers have only a small part of their office and authority.

There were two kinds of ceryces, *civil* and *sacred*. The former were those appointed to call assemblies and make silence therein; also to go on messages, and do the office of our heralds, &c. The sacred ceryces were a sort of priests, whose office was to proclaim silence in the public games and sacrifices, publish the names of the conquerors, proclaim feasts, and the like. The priesthood of the ceryces was annexed to a particular family, the descendants of Ceryx, son of Eumolpus. To them it also belonged to lead solemn victims to slaughter. Before the ceremonies began, they called silence in the assembly, by the formula, *Εὐφημείτω* *αἰὶν πάσι* *ἰσὺ δῖος*; answering to the *favete linguis* of the Romans. When the service was over, they dismissed the people with this formula, *Δαὼν ἀφ᾽ ἑσέως, Ite missa est*.

CESARE, among logicians, one of the modes of the second figure of syllogisms; the minor proposition of which is an universal affirmative, and the other two universal negatives: thus,

CE No immoral books ought to be read;

SA But every obscene book is immoral;

RE Therefore no obscene books ought to be read.

CECENA, a town of Romagna in Italy, with a bishop's see, subject to the pope, and seated on the river Savio, in E. Long. 12. 46. N. Lat. 44. 8.

CESPITOSÆ PLANTÆ (from *cespes*, turf or sod), are those plants which produce many stems from one root, and thence form a close thick carpet on the surface of the earth.

CESPITOSÆ Paludes, turf-bogs.

CESSATION, the act of intermitting, discontinuing or interrupting the course of any thing, work, action, or the like.

CESSATION of Arms, an armistice or occasional truce. See **TRUCE**.

When the commander of a place finds things reduced to an extremity, so that he must either surrender, or sacrifice the garrison and inhabitants to the mercy of the enemy, he plants a white flag on the breach, or beats the chamade; on which a cessation of arms and hostilities commences, to give room for a capitulation.

CESSIO BONORUM, in Scots law, the name of that action by which an insolvent debtor may apply for liberation from prison, upon making over his whole real and personal estate to his creditors.

CESSION, in law, an act by which a person surrenders and transmits to another person a right which belonged to himself. Cession is more particularly used

in the civil law for a voluntary surrender of a person's effects to his creditors, to avoid imprisonment. See the article **BANKRUPT**.

In several places the cession carried with it a mark of infamy, and obliged the person to wear a green cap or bonnet; at Lucca, an orange one: to neglect this was to forfeit the privileges of the *cession*. This was originally intended to signify that the cessionary was become poor through his own folly. The Italian lawyers describe the ceremony of cession to consist in striking the bare breech three times against a stone, called *Lapis Vituperii*, in presence of the judge. Formerly it consisted in giving up the girdles and keys in court: the ancients using to carry at their girdles the chief utensils wherewith they got their living; as the scrivener his *escritoire*, the merchant his bag, &c. The form of cession among the ancient Gauls and Romans was as follows: The cessionary gathered up dust in his left hand from the four corners of the house, and standing on the threshold, holding the door-post in his right hand, threw the dust back over his shoulders; then stripping to his shirt, and quitting his girdle and bags, he jumped with a pole over a hedge; hereby letting the world know, that he had nothing left, and that when he jumped all he was worth was in the air with him. This was the cession in criminal matters. In civil cases, it was sufficient to lay a broom, a switch, or a broken straw, on the threshold: this was called *chrenecruda per durpillum et festucam*.

CESSION, in the ecclesiastical law, is when an ecclesiastical person is created a bishop, or when a parson of a parish takes another benefice, without dispensation, or being otherwise qualified. In both these cases their first benefices became void by cession, without any resignation; and to those livings that the person had, who was created bishop, the king may present for that time, whosoever is patron of them; and in the other case the patron may present: but by dispensation of retainer, a bishop may retain some or all the preferments he was intitled to before he was made bishop.

CESTRUM, **BASTARD JASMINE**: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 28th order, *Lurida*. The corolla is funnel-shaped; the stamina each sending out a little tooth about the middle of the inside. There are six species, all of them natives of the warmest parts of America; so cannot be preserved in this country without artificial heat. They are flowering shrubs, rising in height from five to twelve feet, with flowers of a white, herbaceous, or pale yellow colour. The flowers of one species commonly called *Badmington Jasmine*, have the property of sending out a strong scent after sunset. They may be propagated either by seeds or cuttings.

CESTUI, a French word, signifying *he* or *him*, frequently used in the English law writings. Thus, *Cestui qui trust*, a person who has lands, &c. committed to him for the benefit of another; and if such person does not perform his trust, he is compellable to it in chancery. *Cestui qui vie*, one for whose life any lands, &c. are granted. *Cestui qui use*, a person to whose use any one is infeoffed of lands or tenements. Formerly the feoffees to uses were deemed owners of

the land; but now the possession is adjudged in *cestui qui use*.

CESTUS, among ancient poets, a fine embroidered girdle said to be worn by Venus, to which Homer ascribes the power of charming and conciliating love. The word is also written *cestum* and *ceston*: it comes from *κεστω*, a girdle, or other thing embroidered or wrought with a needle; derived, according to Servius, from *κεστρον*, *pungere*; whence also *incestus*, a term used at first for any indecency by undoing the girdle, &c. but now restrained to that between persons near akin. See INCEST.

CETACEOUS, an appellation given to the fishes of the whale kind; the characters of which are: they have no gills; there is an orifice on the top of the head, through which they breathe and eject water; and they have a flat or horizontal tail.

Nature on this tribe hath bestowed an internal structure in all respects agreeing with that of quadrupeds; and in a few others the external parts in both are similar. Cetaceous fish, like land animals, breathe by means of lungs, being destitute of gills. This obliges them to rise frequently on the surface of the water to respire, to sleep on the surface, as well as to perform several other functions. They have the power of uttering sounds, such as bellowing and making other noises denied to genuine fish. Like land animals they have warm blood, are furnished with organs of generation, copulate, bring forth, and suckle their young, showing a strong attachment to them. Their bodies beneath the skin are entirely surrounded with a thick layer of fat (blubber), analogous to the lard on hogs. The number of their fins never exceed three, *viz.* two pectoral fins, and one back fin; but in some species the last is wanting. Their tails are placed horizontally, or flat in respect to their bodies; contrary to the direction of those of all other fish, which have them in a perpendicular site. This situation of the tail enables them to force themselves suddenly to the surface of the water to breathe, which they are so frequently constrained to do. Many of these circumstances induced Linnæus to place this tribe among his *mammalia*, or what other writers call *quadrupeds* *. To have preserved the chain of beings entire, he should in this case have made the genus of *phoca* or *seals*, and that of the *trichechus* or *manati*, immediately precede the whale, those being the links that connect the *mammalia* or quadrupeds with the fish: for the seal is, in respect to its legs, the most imperfect of the former class; and in the *manati* the hind feet coalesce, assuming the form of a broad horizontal tail.

Notwithstanding the many parts and properties which cetaceous fish have in common with land animals, yet there still remain others which render it more natural to place them, with Ray, in the rank of fish: the form of their bodies agrees with that of fish; they are entirely naked, or covered only with a smooth skin; they live constantly in the water, and have all the actions of fish.

CETE, the name of Linnæus's seventh order of *mammalia*, comprehending the *MONODON*, *BALÆNA*, *PHYSETER*, and *DELPHINUS*.

CETERACH, in botany, the trivial name of a species of *ASPENIUM*.

CETTE, a maritime town of France, in Langue-

doc, seated at the place where the canal of Languedoc begins, between Montpellier and Agde, on the bay of Maguelona in the Mediterranean sea. E. Long. 3. 15. N. Lat. 43. 25.

CETUS, in astronomy, the whale; a large constellation of the southern hemisphere, under Pisces, and next the water of Aquarius. The stars in the constellation Cetus, in Ptolemy's catalogue, are twenty-two; in Tycho's twenty-one; in Hevelius's forty-five; in the Britannic catalogue ninety-seven.

Cetus is represented by the poets, as the sea-monster which Neptune, at the suit of the nymphs, sent to devour Andromeda for the pride of her mother, and which was killed by Perseus. In the mandible of cetus is a variable star which appears and disappears periodically, passing through the several degrees of magnitude both increasing and diminishing, in about 333 days. See ASTRONOMY, n^o 45.

CEVA, a strong town of Piedmont in Italy, seated on the river Tanero, with a strong fort, in E. Long. 8. 8. N. Lat. 44. 20.

CEVENNES, mountains of Languedoc in France, remarkable for the frequent meetings of the Protestants there as a place of security against the tyranny of their governors. In queen Anne's reign there was an attempt made to assist them by an English fleet in the Mediterranean; but to no purpose, for the French had occupied the passages.

CEUTA, a maritime town of Barbary in Africa, and in the kingdom of Fez, seated on the straits of Gibraltar, opposite that place, in W. Long 6. 25. N. Lat. 36. 35. John king of Portugal took it from the Moors in 1415, but it now belongs to Spain. In 1697, it sustained a vigorous siege by the Moors.

CEYLON, a large island in the East Indies, about 250 miles in length and 200 in breadth. It abounds in trees and shrubs, valuable both on account of their timber and the gums or spices they produce. Among these Mr Ives enumerates the euphorbium, tulip-tree, ebony, red-wood, cassia, cocoa-nut, cotton, lime, mangoe, citron, coffee; the trees producing balsam of capivi, gum gamboge, lac, and *cenquenomale*. This last is as yet unknown in Europe; but, according to the information of a Dutch surgeon, an oil or balsam is produced from it by distillation, which is of great use in paralytic complaints. There is also another gum named *badile*, which has been but lately discovered, and of which the use is as yet unknown. Here is also the black and yellow *teak*, the wood of which is of a most beautiful grain, but so hard that the cutting of it proves very destructive to the carpenters tools. But the most remarkable, as well as the most useful, of the vegetable productions of Ceylon, is the cinnamon-tree, which grows wild in every wood on the south-west part of the island. The very young trees are not fit for rinding, and the old ones are cut down for firewood. The common flowering shrubs, of which the whole island is full, send forth a most agreeable fragrance every morning and evening. It abounds with high hills, between which the soil is a fat red earth; and the valleys are extremely pleasant, having a clear rivulet running thro' almost every one of them. Thus the finest fruits grow in vast plenty, and may be had at the most trifling rates; a pine-apple being bought for less than a penny, and so of the rest. Other provisions are almost equally cheap;

Cetus
||
Ceylon.

* See
Zoology.

Ceylon.

cheap; a dozen of fowls or five ducks being sold for a rupee, not quite half-a-crown of English money. Here the Dutch show a poisonous fruit called by them *Adam's apple*. In shape it resembles the quarter of an apple cut out, with the two insides a little convex, and a continued ridge along the outer edges; and is of a beautiful orange colour. Pepper, ginger, and cardamoms, are also produced here; as well as five kinds of rice, which ripen one after another.

Ceylon produces also topazes, garnets, rubies, and other precious stones, which are discovered by washing the soil wherein they grow. It has likewise ores of copper, iron, and probably of tin, with veins of black crystal.

Common deer are found in this island in great abundance, as well as Guinea-deer; but the horned cattle are both very small and scarce, six of them weighed, all together, but 714 pounds, and one of these weighed only 70 pounds. They have, however, the largest and best elephants in the world; and their woods are infested by tygers, the most terrible of all ravenous beasts. They abound also with snakes of a monstrous size, one of which has been known to destroy a tyger and devour him at one meal. Mr Ives saw one 15 feet long and 30 inches in circumference. Spiders, centipedes, and scorpions, also grow here to an enormous size. Our author saw a spider here as large as a toad, with brown hair upon it, and legs as thick as the shank of a large tobacco-pipe. A scorpion, taken out of a piece of wood, was eight inches long, from head to tail, exclusive of the claws; the shell was as hard as that of a crab: and our author killed a centipede more than seven inches long. Here the *mantis* or creeping leaf is met with; which our author supposes to be a species of grasshoppers, having every member we see in common insects, though in shape and appearance it greatly resembles a leaf. It is of a green colour. The sea-coasts abound with fish, which are to be had very cheap. Neither harp-shells nor ventle-traps are to be met with here: but there are abundance of painted cockles, and others commonly called *panama shells*.

"The natives of this island (says our author) are the stoutest Indians I ever saw. Mr Knox in his history reports many strange things of their religion and customs, none of which I had any opportunity of seeing. He says 'that they have various ways of treating their dead. Some burn them, which is not uncommon in India; while others throw their limbs up into the forks of trees.' This may be true, because when our wood-cutters were once hewing down a stick of timber, there fell from it the skull and many bones of a human body; and I also saw here a human body hanging on a tree. Other historians relate, that the natives of Ceylon feed on human flesh: nay, that they eat the bodies of their deceased parents, imagining that no other sepulchre is so fit for them as their own bowels, since thereby they think they are changed into their own substance, and live again in themselves. This shocking custom is reported of the ancient Scythians, and possibly might have been used by the inhabitants of Ceylon, but is now in both countries entirely abolished; and yet even at this day these islanders are said to make cups of their parents skulls, with a

view, that in midst of their mirth and jollity they may be sure to preserve a respectful remembrance of them."

Ceylon.

The Ceylonefe make use of boats hollowed out of the trunks of trees, which are about 12 or 14 feet long, but only as many inches broad within. The tree part in the bottom is much larger; but when the boat, on account of the size of the tree, is too small, they make a trough on the top of it square at both ends. Some boats, however, are much larger, being built between two trees; and with these they coast along shore; the others are for fishermen. It lies from E. Long. 78° to 82°, and from N. Lat. 6° to 10.

The conquest of this island was the first attempt of Albuquerque the celebrated Portuguese admiral. He found it well peopled, and inhabited by two different nations, the *Bedas* inhabiting the northern, and the *Cinglaffes* who dwelt in the southern parts. The former were very barbarous, but the latter a good deal more polished. Besides the advantages already mentioned, which these nations derived from their mines of precious stones, they carried on the greatest pearl-fishery in the East. These nations the Portuguese conquered, and tyrannized over in such a manner, that they assisted the Dutch in expelling them from the island; and by their united efforts this was accomplished in 1658, after a bloody and obstinate war. All the Portuguese settlements fell into the hands of the Dutch East India company, who still keep possession of them, excepting a small district on the eastern coast without any port, from whence the sovereign of the country had his salt. These settlements formed a regular track, extending from two to twelve leagues into the inland parts of the island. The company have appropriated all the productions of the island. The several articles of trade are, 1. Amethysts, sapphires, topazes, and rubies; the last are very small, and very indifferent. The Moors who come from the coast of Coromandel buy them, paying a moderate tax: and when they are cut, sell them at a low price in the different countries of India. 2. Pepper, which the company buy for about 4d. *per* pound; coffee, for which they only pay 2d. and cardamom, which has no fixed price. These articles are all of an inferior quality, and through the indolence of the inhabitants will never turn to any account. 3. An hundred bales of handkerchiefs, pagnes, and gingham, of a fine red colour, which are fabricated by the Malabars at Jafra-napatan. 4. A small quantity of ivory, and about 50 elephants, which are carried to the coast of Coromandel. 5. Areca, which the company buys at about 8s. 9d. the ammonan, and sells on the spot at L. 1, 13s. to the merchants of Bengal, Coromandel, and the Maldives; who give in return rice, coarse linen, and cowries. 6. The pearl-fishery, which was formerly of great consequence; but is now so much exhausted as not to bring in more than L. 8,750 *per annum*. 7. After all, the great object of the company is cinnamon. They purchase the greatest part of their cinnamon of the Indians who are subject to them, and, all expences deducted, it does not cost them above 6d. *per* pound. The annual expences of the colony may amount to about L. 96,250; their revenues and small branches of commerce produce only about L. 87,500. —This deficiency must be supplied out of the profits

Chace
||
Charonea.

fits arising from the cinnamon trade; and they are obliged to provide for the expences of the wars in which they are frequently engaged with the king of Candy, who is at present the sole sovereign of the island. These are very detrimental to the interests of the Hollanders; for which reason they endeavoured to engage the good will of this monarch by showing him all imaginable civilities. The harmony, however, has been often interrupted. In a bloody war which terminated on the 14th of February 1766, the Ceylonese monarch was driven from his capital, so that the Dutch made a very advantageous treaty. Their sovereignty was acknowledged over all that part of the country they possessed before the troubles broke out; and that part of the coasts held by the natives was ceded to them. They were allowed to gather cinnamon in all the plains; and the court was to sell them the best sort, which is produced in the mountains, at the rate of L. 1:16:1, for 18 lb. The government engaged to have no connection with any foreign power; and even to deliver up any Europeans who might happen to stray into the island. In return for so many concessions, the king was to receive annually the value of the produce of the ceded coasts; and from thence his subjects were to be furnished gratis with as much salt as they had occasion for. The Ceylonese are in the most miserable situation: they are in a state of total inactivity; live in huts without any furniture; and subsist upon fruits: those who are the most affluent have no other covering than a piece of coarse linen wrapt about their waist.

CHACE. See CHASE.

CHACO, a large country of South America situated between 19° and 37° S. Lat. It belongs to the Spaniards, by whom it was conquered in 1536. It is not naturally fruitful; but abounds in gold mines, which are so much the more valuable that they are easily worked. The works are carried on by about 8000 blacks, who deliver every day to their masters a certain quantity of gold; and what they can collect above this, belongs to themselves; as well as what they find on those days that are consecrated to religion and rest, upon condition that during the festival they maintain themselves. This enables many of them to purchase their liberty; after which they intermarry with the Spaniards.

CHADCHOD, in Jewish antiquity. Ezekiel mentions *chadchod* among the several merchandizes which were brought to Tyre. The old interpreters, not very well knowing the meaning of this term, continued it in their translation. St Jerom acknowledges that he could not discover the interpretation of it. The Chaldee interprets it pearls; others think that the onyx, ruby, carbuncle, crystal, or diamond is meant by it.

CHÆRONEA, (anc. geog.), the last town, or rather the last village, of Bœotia, towards Phocis; the birthplace of Plutarch: famous for the fatal defeat of the confederate Greeks by Philip of Macedon. This place was considered by Philip as well adapted to the operations of the Macedonian phalanx; and the ground for his encampment, and afterwards the field of battle, were chosen with equal sagacity: having in view on one side a temple of Hercules, whom the Macedonians

regarded as the author of their royal house, and the high protector of their fortune; and on the other the banks of the Thermodon, a small river flowing into the Cephissus, announced by the oracles of Greece as the destined scene of desolation and woe to their unhappy country. The generals of the confederate Greeks had been much less careful to avail themselves of the powerful sanctions of superstition. Unrestrained by inauspicious sacrifices, the Athenians had left their city at the exhortation of Demosthenes, to wait no other omen but the cause of their country. Regardless of oracles, they afterwards advanced to the ill-fated Thermodon, accompanied by the Thebans, and the scanty reinforcements raised by the islands and states of Peloponnesus which had joined their alliance. Their army amounted to 30,000 men, animated by the noblest cause for which men can fight, but commanded by the Athenians Lyficles and Chares; the first but little, and the second unfavourably known; and by Theagenes the Theban, a person strongly suspected of treachery: all three creatures of cabal and tools of faction, slaves of interest or voluptuousness, whose characters (especially as they had been appointed to command the only states whose shame, rather than virtue, yet opposed the public enemy) are alone sufficient to prove that Greece was ripe for ruin.

When the day approached for abolishing the tottering independence of those turbulent republics, which their own internal vices, and the arms and intrigues of Philip, had been gradually undermining for 22 years, both armies formed in battle array before the rising of the sun. The right wing of the Macedonians was headed by Philip, who judged proper to oppose in person the dangerous fury of the Athenians. His son Alexander, only 19 years of age, but surrounded by experienced officers, commanded the left wing, which faced the Sacred Band of the Thebans. The auxiliaries of either army were posted in the centre. In the beginning of the action, the Athenians charged with impetuosity, and repelled the opposing divisions of the enemy; but the youthful ardour of Alexander obliged the Thebans to retire, the Sacred Band being cut down to a man. The activity of the young prince completed their disorder, and pursued the scattered multitude with his Thessalian cavalry.

Meantime the Athenian generals, too much elated by their first advantage, lost the opportunity to improve it; for having repelled the centre and right wing of the Macedonians, except the phalanx, which was composed of chosen men, and immediately commanded by the king, they, instead of attempting to break this formidable body by attacking it in flank, pressed forward against the fugitives, the insolent Lyficles exclaiming in vain triumph, "Pursue, my brave countrymen! let us drive the cowards to Macedon." Philip observed this rash folly with contempt; and saying to those around him, "Our enemies know not how to conquer," commanded his phalanx, by a rapid evolution, to gain an adjacent eminence, from which they poured down, firm and collected, on the advancing Athenians, whose confidence of success had rendered them totally insensible to danger. But the irresistible shock of the Macedonian spear converted their fury into despair. Above a thousand fell, two thousand were taken prisoners.

Charonea. soners; the rest escaped by a precipitate and shameful flight. Of the Thebans more were killed than taken. Few of the confederates perished, as they had little share in the action, and as Philip, perceiving his victory to be complete, gave orders to spare the vanquished, with a clemency unusual in that age, and not less honourable to his understanding than his heart; since his humanity thus subdued the minds, and gained the affections, of his conquered enemies.

According to the Grecian custom, the battle was followed by an entertainment, at which the king presiding in person, received the congratulations of his friends, and the humble supplications of the Athenian deputies, who craved the bodies of their slain. Their request, which served as an acknowledgment of their defeat, was readily granted; but before they availed themselves of the permission to carry off their dead, Philip, who with his natural intemperance had protracted the entertainment till morning, issued forth with his licentious companions to visit the field of battle; their heads crowned with festive garlands, their minds intoxicated with the insolence of wine and victory; yet the sight of the slaughtered Thebans, which first presented itself to their eyes, and particularly the sacred band of friends and lovers, who lay covered with honourable wounds on the spot where they had been drawn up to fight, brought back these insolent spectators to the sentiments of reason and humanity. Philip beheld the awful scene with a mixture of admiration and pity; and, after an affecting silence, denounced a solemn curse against those who basely suspected the friendship of such brave men to be tainted with criminal and infamous passions.

But this serious temper of mind did not last long; for having proceeded to that quarter of the field where the Athenians had fought and fallen, the king abandoned himself to all the levity and littleness of the most petulant joy. Instead of being impressed with a deep sense of his recent danger, and with dutiful gratitude to Heaven for the happiness of his escape and the importance of his victory, Philip only compared the boastful pretensions with the mean performances of his Athenian enemies; and, struck by this contrast, retheatred, with the insolent mockery of a buffoon, the pompous declaration of war lately drawn up by the ardent patriotism and too sanguine hopes of Demophenes. It was on this occasion that the orator Demades at once rebuked the folly, and flattered the ambition, of Philip, by asking him, Why he assumed the character of Therfites when fortune assigned him the part of Agamemnon?

Whatever might be the effect of this sharp reprimand, it is certain that the king of Macedon indulged not, on any future occasion, a vain triumph over vanquished. When advised by his generals to advance into Attica, and to render himself master of Athens, he only replied, "Have I done so much for glory, and shall I destroy the theatre of that glory?" His subsequent conduct corresponded with the moderation of this sentiment. He restored without ransom the Athenian prisoners; who, at departing, having demanded their baggage, were also gratified in this particular; the king pleasantly observing, that the Athenians seemed to think he had not conquered them in earnest. Soon afterwards he dispatched his son Alexander, and

Antipater, the most trusted of his ministers, to offer them peace on such favourable terms as they had little reason to expect. They were required to send deputies to the Isthmus of Corinth, where, to adjust their respective contingents of troops for the Persian expedition, Philip purposed assembling early in the spring a general convention of all the Grecian states: they were ordered to surrender the isle of Samos, which actually formed the principal station of their fleet, and the main bulwark and defence of all their maritime or insular possessions; but they were allowed to enjoy, unmolested, the Attic territory, with their hereditary form of government.

CHÆROPHYLLUM, CHERVIL: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellatae*. The involucre is reflexed-concave; the petals inflexed-cordate; the fruit oblong and smooth. There are seven species, two of which, called cow-weed and wild chervil, are weeds common in many places of Britain. The roots of the first have been found poisonous when used as parsnips: the rundles afford an indifferent yellow dye; the leaves and stalks a beautiful green. Its presence indicates a fertile and grateful soil. It ought to be rooted out from all pastures early in the spring, as no animal but the ass will eat it. It is one of the most early plants in shooting, so that by the beginning of April the leaves are near two feet high. The leaves are recommended by Geoffroy as aperient and diuretic, and at the same time grateful to the palate and stomach. He even asserts, that dropsies which do not yield to this medicine can scarcely be cured by any other. He directs the juice to be given in the dose of three or four ounces every fourth hour, and continued for some time either alone, or in conjunction with nitre and syrup of the five opening roots.—The other species of *chærophylum* are not possessed of any remarkable property.

CHÆTODON, in ichthyology, a genus of fishes belonging to the order of thoraci. The teeth are very numerous, thick, setaceous, and flexile; the rays of the gills are six. The back-fin and the fin at the anus are fleshy and squamous. There are 23 species, distinguished from each other principally by the figure of the tail, and the number of spines in the back-fin. The most remarkable is the *rostratus*, or shooting-fish, having a hollow, cylindrical beak. It is a native of the East Indies, where it frequents the sides of the sea and rivers in search of food, from its singular manner of obtaining which it receives its name. When it spies a fly sitting on the plants that grow in shallow water, it swims on to the distance of four, five, or six feet; and then, with a surprising dexterity, it ejects out of its tubular mouth a single drop of water, which never fails striking the fly into the water, where it soon becomes its prey.

CHAFF, in husbandry, the husks of the corn, separated by screening or winnowing it. It signifies also the rind of corn, and straw cut small for the use of cattle.

CHAFF-Cutter, a machine for making chaff to feed horses.—The advantages of an easy and expeditious method of cutting straw into chaff by an engine which could be used by common labourers have been long

Chæro-
phyllum

Chaffery.

long acknowledged, and various attempts have been made to bring such an engine to perfection. But the objections to most of them have been their complicated structure, their great price, and the noise they make in working; all which inconveniences seem to have been lately removed by an invention of Mr James Pike watchmaker of Newton Abbot in Devonshire. Of his engine, which is of a simple and cheap construction, the following description, and figure referred to, are extracted from the Transactions of the Society of Arts for 1787.

The engine is fixed on a wood frame, which is supported with four legs, and on this frame is a box for containing the straw, four feet six inches long, and about ten inches broad; at one end is fixed across the box two rollers inlaid with iron, in a diagonal line about an eighth of an inch above the surface; on the ends of these rollers are fixed two strong brass wheels, which takes one into the other. On one of these wheels is a contract wheel, whose teeth take in a worm on a large arbour; on the end of this arbour is fixed a wooden wheel, two feet five inches diameter and three inches thick; on the inside-part of this wheel is fixed a knife, and every revolution of the wheel the knife passes before the end of the box and cuts the chaff, which is brought forward between the rollers, which are about two inches and a half asunder; the straw is brought on by the worm taking one tooth of the wheel every round of the knife; the straw being so hard pressed between the rollers, the knife cuts off the chaff with so great ease, that twenty-two bushels can be cut within the hour, and makes no more noise than is caused by the knife passing through the chaff.

Plate
CXXXVI.

A is the box into which the straw is put. *B*, the upper roller, with its diagonal projecting ribs of iron, the whole moving by the revolution of the brass wheel *C* on the axis of which it is fixed. *D*, a brass wheel, having upon it a face wheel, whose teeth take into the endless screw on the arbor *E*, while the teeth on the edge of this wheel enter between those on the edge of the wheel *C*. On the axis of the wheel *D* is a roller, with iron ribs similar to *B*, but hid within the box. *E*, the arbor, one of the ends of which being made square and passing through a mortise in the centre of the wooden wheel *F*, is fastened by a strong screw and nut; the other end of this arbor moves round in a hole within the wooden block *G*. *H*, the knife, made fast by screws to the wooden wheel *F*, and kept at the distance of nearly three quarters of an inch from it by means of a strip of wood of that thickness, of the form of the blade, and reaching to within an inch of the edge. *I*, the handle mortised into the outside of the wooden wheel *F*.

CHAFFER, in zoology, a species of beetle. See SCARABÆUS.

CHAFFERCONNERS, in commerce, printed linens manufactured in the Great Mogul's dominions. They are imported by the way of Surat; and are of the number of those linens prohibited in France.

CHAFFERY, in the iron-works, the name of one of the two principal forges. The other is called the finery. When the iron has been brought at the finery into what is called an ancony, or square mass, hammered into a bar in its middle, but with its two ends rough, the business to be done at the chaffery is

Vol. IV. Part I.

the reducing the whole to the same shape, by hammering down these rough ends to the shape of the middle part.

CHAFFINCH, in ornithology, the English name of a species of FRINGILLA.

CHAGRE, a fort of America in the province of Darien at the mouth of a river of the same name. It has been taken several times by the buccaneers, and last of all by Admiral Vernon in 1740. W. Long. 82. 7. N. Lat. 9. 50.

CHAIN (*Catena*), a series of several rings, or links, fitted into one another.

There are chains of divers matters, sizes, forms, and for divers uses.—Ports, rivers, streets, &c. are closed with iron chains: rebellious cities are punished by taking away their chains and barriers.

The arms of the kingdom of Navarre are, *Chains Or, in a field Gules*. The occasion hereof is referred to the kings of Spain leagued against the Moors; who having gained a celebrated victory against them in 1212, in the distribution of the spoils the magnificent tent of Miralminum fell to the king of Navarre, as being the first that broke and forced the chains thereof.

A gold CHAIN, is one of the ornaments or badges of the dignity of the chief magistrates of a city, as the mayor of London, the provost and bailies of Edinburgh, &c.—Something like this obtained among the ancient Gauls: the principal ornament of their persons in power and authority was a gold chain, which they wore on all occasions; and even in battle, to distinguish them from the common soldiers.

CHAIN also denotes a kind of string, of twisted wire; serving to hang watches, tweezer-cases, and other valuable toys upon. The invention of this piece of curious work is owing to the English; whence, in foreign countries, it is denominated the *English chain*. These chains are usually either of silver or gold, some of gilt copper; the thread or wire of each kind to be very fine.—For the fabric, or making of these chains: a part of the wire is folded into little links of an oval form; the longest diameter about three lines; the shortest, one. These, after they have been exactly foldered, are again folded into two; and then bound together or intervove, by means of several other little threads of the same thickness; some whereof, which pass from one end to the other, imitate the warp of a stuff; and the others, which pass transverse, the woof. There are at least four thousand little links in a chain of four pendants; which are by this means bound so equally, and withal so firmly together, that the eye is deceived, and takes the whole to consist of one entire piece.

CHAIN is also a kind of measure in France, in the trade of wood for fuel. There are chains for wood by tale, for wood by the rope, for faggots, for cleft wood, and for round sticks. There are also chains for measuring the sheaves of all sorts of corn, particularly with regard to the payment of tithes; for measuring pottles of hay, and for measuring horses. All these are divided into feet, inches, hands, &c. according to the use they are designed for.

CHAIN, in surveying, is a measure, consisting of a certain number of links of iron wire, usually a hundred; serving to take the dimensions of fields, &c.

R r

Chaffinch
||
Chain.

Chains. This is what Merfenne takes to be the arripendum of the ancients.

The chain is of various dimensions, as the length or number of links varies: that commonly used in measuring land, called Gunter's chain, is in length four poles or perches; or sixty-six feet, or a hundred links; each link being seven inches $\frac{9}{10}$. Whence it is easy to reduce any number of those links to feet, or any number of feet to links.

This chain is entirely adapted to English measures; and its chief convenience is in finding readily the numbers contained in a given field. Where the proportions of square feet and acres differ, the chain, to have the same advantages as Gunter's chain, must also be varied. Thus in Scotland, the chain ought to be of 74 feet, or 24 Scotch ells, if no regard be had to the difference between the Scotch and English foot; but if regard be had to this difference, the Scotch chain ought to consist of $74\frac{2}{3}$ English feet, or 74 feet 4 inches and $\frac{2}{3}$ of an inch. This chain being divided into an hundred links, each of these will be $8\frac{2}{10}$ inches.

That ordinarily used for large distances, is in length a hundred feet; each link one foot. For small parcels, as gardens, &c. is sometimes used a small chain of one pole, or sixteen feet and a half length; each link one inch $\frac{9}{10}$.

Some in lieu of chains use ropes; but these are liable to several irregularities; both from the different degrees of moisture, and of the force which stretches them. Schwenterus, in his Practical Geometry, tells us, he has observed a rope sixteen feet long, reduced to fifteen in an hour's time, by the mere falling of a hoar frost. To obviate these inconveniences, Wolfius directs, that the little strands whereof the rope consists be twisted contrary ways, and the rope dipped in boiling hot oil; and when dry, drawn through melted wax. A rope thus prepared, will not get or lose any thing in length, even though kept under water all day.

CHAIN-Pump. See PUMP.

CHAIN-Shot, two bullets with a chain between them. They are used at sea to shoot down yards or masts, and to cut the shrouds or rigging of a ship.

Top-CHAIN, on board a ship, a chain to sling the sail-yards in time of battle, in order to prevent them from falling down when the ropes by which they are hung happen to be shot away or rendered incapable of service.

Plate CXXXVI. **CHAIN-Wales,** or *Channels*, of a ship, *porteboissiers*, are broad and thick planks projecting horizontally from the ship's outside, abreast of and somewhat behind the masts. They are formed to extend the shrouds from each other, and from the axis or middle line of the ship, so as to give a greater security and support to the masts, as well as to prevent the shrouds from damaging the gunwale, or being hurt by rubbing against it. Every mast has its chain-wales, which are either built above or below the second deck-ports in a ship of the line: they are strongly connected to the side by knees, bolts, and standards, besides being confined thereto by the chains whose upper ends pass through notches on the outer edge of the chain-wales, so as to unite with the shrouds above.

CHAINS, in ship-building, are strong links or plates

of iron, the lower ends of which are bolted through the ship-side to the timbers.

Hanging in CHAINS, a kind of punishment inflicted on murderers. By stat. 25. Geo. II. c. 37. the judge shall direct such to be executed on the next day but one, unless Sunday intervene; and their bodies to be delivered to the surgeons to be dissected and anatomized: and he may direct them afterwards to be hung in chains. During the interval between sentence and execution, the prisoner shall be kept alone, and sustained only with bread and water. The judge, however, hath power to respite the execution, and relax the other restraints of the act.

CHAIN-Island, an island lately discovered by captain Wallis in the South-sea. It seemed to be about five miles long and as much broad, lying in the direction of north-west and south-east. It appeared to be a double range of woody islands joined together by reefs, so as to compose one island of an oval figure, with a lake in the middle. The trees are large; and from the smoke that issued from the woods, it appeared to be inhabited. W. Long. 145. 54. S. Lat. 17. 23.

CHAJOTLI, or **CHAYOTI,** a Mexican fruit of a round shape, and similar in the husk with which it is covered to the chestnut, but four or five times larger, and of a much deeper green colour. Its kernel is of a greenish white, and has a large stone in the middle, which is white, and like it in substance. It is boiled, and the stone eat with it. This fruit is produced by a twining perennial plant, the root of which is also good to eat. See Plate CXXXVIII.

CHAIR, (*Cathedra*), was anciently used for the pulpit, or *suggestum*, whence the priest spoke to the people.

It is still applied to the place whence professors and regents in universities deliver their lectures, and teach the sciences to their pupils: thus, we say, the professor's chair, the doctor's chair, &c.

Curule CHAIR, was an ivory seat placed on a car, wherein were seated the prime magistrates of Rome, and those to whom the honour of a triumph had been granted.

Sedan CHAIR, a vehicle supported by poles, wherein persons are carried; borne by two men. There are two hundred chairs allowed by act of parliament; and no person is obliged to pay for a hackney-chair more than the rate allowed by the act for a hackney-coach driven two third parts of the said distance. 9 Ann. c. 23. § 8. Their number is since increased, by 10 Ann. c. 19. and 12 Geo. I. c. 12. to four hundred. See *Hackney-COACHES*.

CHAIR is also applied by the Romanists to certain feasts, held anciently in commemoration of the translation of the see, or seat of the vicarage of Christ, by St Peter.

The perforated chair, wherein the new-elected pope is placed, F. Mabillon observes, is to be seen at Rome: but the origin thereof he does not attribute, as is commonly done, to the adventure of Pope Joan; but says there is a mystery in it; and it is intended, forsooth, to explain to the pope those words of scripture, that *God draws the poor from out of the dust and mire*.

CHAIRMAN, the PRESIDENT, or speaker of an assembly,

||
Chalcedo-
ny.

assembly, company, &c. We say, the chairman of a committee, &c.

CHAISE, a sort of light open chariot, or calash. Aurelius Victor relates, that Trajan first introduced the use of post-chaises: but the invention is generally ascribed to Augustus; and was probably only improved by Trajan, and succeeding emperors.

CHALAZA, among naturalists, a white knotty sort of string at each end of an egg, formed of a plexus of the fibres of the membranes, whereby the yolk and white are connected together. See EGG.

CHALCAS, in botany: A genus of the monogynia order, belonging to the pentandria class of plants. The calyx is quinquepartite; the corolla campanulate, with the petals heeled; the stigma round-headed and warty.

CHALCEDON, or CALCEDON, anciently known by the names of *Procerastis* and *Colbusa*; a city of Bithynia, situated at the mouth of the Euxine, on the north extremity of the Thracian Bosphorus, over against Byzantium. Pliny, Strabo, and Tacitus, call it *The City of the Blind*; alluding to the answer which the Pythian Apollo gave to the founders of Byzantium, who, consulting the oracle relative to a place where to build a city, were directed to choose that spot which lay opposite "to the habitation of the blind;" that is, as was then understood, to Chalcedon: the Chalcedonians well deserving that epithet for having built their city in a barren and sandy soil, without seeing that advantageous and pleasant spot on the opposite shore, which the Byzantines afterwards chose.—Chalcedon, in the Christian times, became famous on account of the council which was held there against Eutyches. The emperor Valens caused the walls of this city to be levelled with the ground for siding with Procopius, and the materials to be conveyed to Constantinople, where they were employed in building the famous Valentinian aqueduct. Chalcedon is at present a poor place, known to the Greeks by its ancient name, and to the Turks by that of *Cadiaci*, or "the judges town."

CHALCEDONY, in natural history, a genus of the semipellucid gems. They are of an even and regular, not tabulated structure; of a semi-opaque crystalline basis; and variegated with different colours, but those ever disposed in form of mists or clouds, and, if nicely examined, found to be owing to an admixture of various coloured earths, but imperfectly blended in the mass, and often visible in distinct molecules.—It has been doubted by some whether the ancients were at all acquainted with the stone we call *chalcedony*; they having described a Chalcedonian carbuncle and emerald, neither of which can at all agree with the characters of our stone; but we are to consider that they have also described a Chalcedonian jasper which seems to have been the very same stone as they describe by the word *turbida*, which extremely well agrees with our chalcedony.

There are four known species of the chalcedony. 1. A bluish white one. This is the most common of all, and is found in the shape of our flints and pebbles, in masses of two or three inches or more in diameter. It is of a whitish colour, with a faint cloud of blue diffused all over it, but always in the greatest degree near the surface. This is a little less hard than the oriental onyx. The oriental chalcedonies are the

only ones of any value; they are found in vast abundance on the shores of rivers in all parts of the East Indies, and frequently come over among the ballast of the East India ships. They are common in Silesia and Bohemia, and other parts of Europe also; but with us are less hard, more opaque, and of very little value. 2. The dull milky-veined chalcedony. This is a stone of little value; and is sometimes met with among our lapidaries, who mistake it for a kind of nephritic stone. It is of a somewhat yellowish white or cream colour, with a few milk-white veins. This is principally found in New Spain. 3. The third is a brownish, black, dull, and cloudy one, known to the ancients by the name of smoky jasper, or *jaspis capnitis*. This is the least beautiful stone of all the class: it is of a pale brownish white, clouded all over with a blackish mist, as the common chalcedony is with a blue. It is common both in the East and West Indies, and in Germany; but is very little valued, and is seldom worked into any thing better than the handles of knives. 4. The yellow and red chalcedony is greatly superior to all the rest in beauty; and is in great repute in Italy, though very little known among us. It is naturally composed of an admixture of red and yellow only, on a clouded crystalline basis; but is sometimes found blended with the matter of common chalcedony, and then is mixed with blue. It is all over of the misty hue of the common chalcedony. This is found only in the East Indies, and there not plentifully. The Italians make it into beads, and call these *cassidones*; but they are not determinate in the use of the word, but call beads of several of the agates by the same name.—All the chalcedonies readily give fire with steel, and make no effervescence with aquafortis.

CHALCIDENE, or CHALCIDICE, (anc. geog.) an inland country of Syria, having Antiochis or Seleucia to the west, Cyrrhestica to the north, to the south Apamene and Coele Syria, and to the east Chalybonitis; being so called from its principal city Chalcis. This province, one of the most fruitful in Syria, was seized by Ptolemy the son of Menæus during the troubles of Syria, and by him made a separate kingdom. Ptolemy himself is styled by Josephus and Hegesippus only Prince of Chalcis, but his son Lyfanius is honoured both by Josephus and Dio with the title of King. Upon the death of Antiochus Dionysius king of Syria, Ptolemy attempted to make himself master of Damascus and all Coele Syria; but the inhabitants, having an utter aversion to him on account of his cruelty and wickedness, chose rather to submit to Aretas king of Arabia, by whom Antiochus and his whole army had been cut off. He opposed Pompey on his entering Syria; but was by him defeated, taken prisoner, and sentenced to death; which, however, he escaped by paying a thousand talents, and was left also in the possession of his kingdom. After Aristobulus king of Judæa had been poisoned by the friends of Pompey, and Alexander his son beheaded at Antioch, he sent Philippion his son to Ascalon, whither the widow of Aristobulus had retired with her other children, to bring them all to Chalcis; proposing, as he was in love with one of the daughters named Alexandria, to maintain them in his own kingdom in a manner suitable to their rank: but Philippion like-

Chalcedo-
ny,
Chalcidene.

Chalcidic
||
Chalcondylas.

wife being in love with Alexandria, married her on the way; for which presumption Ptolemy put him to death on his return, and then took her to wife. On account of this affinity, he supported to the utmost of his power Antigonus the younger son of Aristobulus, who took the field at the head of a considerable army, but on his entering Judæa was entirely defeated by Herod. Ptolemy soon after died, and was succeeded by his son Lyfanius; who, espousing the cause of the Asmonæan family with great warmth, promised to Barzapharnes who commanded the Parthian troops in Syria, and to Pacorus the king's son, a thousand talents and five hundred women, provided they should put Antigonus in possession of the kingdom of Judæa, and depose Hyrcanus. He was not long after put to death by Marc Antony, at the instigation of Cleopatra; who, in order to have his dominions, accused him falsely of having entered into an alliance with the Parthians.

CHALCIDIC, **CHALCIDICUM**, or **CHALCEDONIUM**, in the ancient architecture, a large magnificent hall belonging to a tribunal or court of justice.—Festus says, it took its name from the city Chalcis; but he does not give the reason. Philander will have it to be the court or tribunal where affairs of money and coinage were regulated; so called from *χαλκος* *brass*, and *δικη* *justice*. Others say, the money was struck in it; and derive the word from *χαλκος*, and *οικος*, *house*. In Vitruvius, it is used for the auditory of a basilica; in other of the ancient writers for a hall or apartment where the heathens imagined their gods to eat.

CHALCIDICE, (anc. geog.) an eastern district of Macedonia, stretching northwards between the Sinus Toronæus and Singiticus. Formerly a part of Thrace, but invaded by Philip of Macedon. Named from the city Chalcis near Olynthus.

CHALCIDIUS, a famous platonic philosopher in the third century, who wrote a commentary, which is esteemed, on the *Timæus* of Plato. This work has been translated from the Greek into Latin.

CHALCIS, a city of Chalcidice. See **CHALCIDICE**. (anc. geog.)—Another of *Ætolia*, near the mouth of the river Evenus, on the Ionian Sea, at the foot of a cognominal mountain; and therefore called by some *Hypochalcis*.—Another of *Eubœa* (Strabo), on the Euripus, the country of Lycophron the poet, one of the seven which formed the constellation Pleiades. Now *Negroponte*. E. Long. 24. 30. Lat. 38. 30.—A fourth, the capital of Chalcidene in Syria; distinguished by the surnames *ad Belum*, a mountain or a river; and *ad Libanum*, from its situation (Pliny).

CHALCITIS, one of the divisions or districts of Mesopotamia, to the south of Anthemusia, the most northern district, next to Armenia, and situated between Edeffa and Carræ. *Chalcitis* (Pliny), an island opposite to Chalcedon.

CHALCONDYLAS (Demetrius), a learned Greek, born at Constantinople, left that city after its being taken by the Turks, and afterwards taught Greek in several cities in Italy. He composed a Greek grammar; and died at Milan in 1513.

CHALCONDYLAS (Laonicus), a famous Greek historian of the 15th century, was born at Athens; and wrote an excellent history of the Turks, from Ottoman, who reigned about the year 1300, to Mahomet II. in 1463.

CHALDEA (anc. geog.), taken in a larger sense, included Babylonia; as in the prophecies of Jeremiah and Ezekiel. In a restricted sense, it denoted a province of Babylonia, towards Arabia Deserta; called in Scripture *The land of the Chaldeans*. Named from Chased the fourth son of Nahor. See **BABYLONIA**.

CHALDEE LANGUAGE, that spoken by the Chaldeans, or people of Chaldea. It is a dialect of the **HEBREW**.

CHALDEE Paraphrase, in the rabbinical style, is called **TARGUM**. There are three Chaldee paraphrases in Walton's Polyglot; viz. that of Onkelos, that of Jonathan son of Uziel, and that of Jerusalem.

CHALDRON, a dry English measure, consisting of thirty six bushels, heaped up according to the sealed bushel kept at Guildhall, London: but on ship-board, twenty-one chaldrons of coals are allowed to the score. The chaldron should weigh two thousand pounds.

CHALICE, the cup or vessel used to administer the wine in the sacrament, and by the Roman Catholics in the mass.

The use of the chalice, or communicating in both kinds, is by the church of Rome denied to the laity, who communicate only in one kind, the clergy alone being allowed the privilege of communicating in both kinds.

CHALK, *Creta*, is a white earth found plentifully in Britain, France, Norway, and other parts of Europe, said to have been anciently dug chiefly in the island of Crete, and thence to have received its name of *Creta*. They have a very easy way of digging chalk in the county of Kent in England. It is there found on the sides of hills; and the workmen undermine it so far as appears proper; then digging a trench at the top as far distant from the edge as the undermining goes at bottom, they fill this with water, which soaks through in the space of a night, upon which the whole flake falls down at once. In other parts of the kingdom, chalk generally lies deeper, and they are forced to dig for it at considerable depths, and draw it up in buckets.

Chalk is of two kinds; hard, dry, and firm, or soft and unctuous; both of which are adapted to various purposes. The hard and dry kind is much the properest for burning into lime; but the soft and unctuous chalk is best for using as a manure for lands. Chalk, whether burnt into lime or not, is in some cases an excellent manure. Its mode of operating on the soil is explained under the article **AGRICULTURE**, n° 20, 25, &c.

Pure chalk melts easily with alkali and flint into a transparent colourless glass. With alkaline salts it melts somewhat more difficultly, and with borax somewhat more easily, than with flint or sand. It requires about half its weight of borax, and its whole weight of alkali, to fuse it. Sal mirabile, and sandi-ver, which do not vitrify at all with the crystalline earths, form, with half their weight of chalk, the first a yellowish black, the latter a greenish, glass. Nitre, on the other hand, one of the most active fluxes for flint, does not perfectly vitrify with chalk. This earth notably promotes the vitrification of flint; a mixture of the two requiring less alkali than either of them separately. If glass made from flint and alkali is further

Chaldea
||
Chalk.

Chalk.

ther saturated with the flint, so as to be incapable of bearing any further addition of that earth without becoming opaque and milky, it will still in a strong fire take up a considerable proportion, one-third or one-fourth of its weight, of chalk, without injury to its transparency; hence chalk is sometimes made use of in compositions for glass, as a part of the salt may then be spared. Chalk likewise has a great effect in melting the stony matters intermixed with metallic ores, and hence might be of use in smelting ores; as indeed limestone is used for that purpose. But it is remarkable, that chalk, when deprived of its fixed air, and converted into limestone, loses much of its disposition to vitrify. It is then found to melt very difficultly and imperfectly, and to render the glass opaque and milky.

Chalk readily imbibes water; and hence masses of it are employed for drying precipitates, lakes, earthy powders that have been levigated with water, and other moist preparations. Its æconomical uses in cleaning and polishing metalline or glass utensils are well known. In this case it is powdered and washed from any gritty matter it may contain, and is then called *whiting*.—In medicine it is one of the most useful absorbents, and is to be looked upon simply as such. The astringent virtues which some have attributed to it have no foundation, unless in as far as the earth is saturated with an acid, with which it composes a saline concrete manifestly sub-astringent. For the further properties of chalk, see *CHEMISTRY, Index*.

Black CHALK, a name given by painters to a species of earth with which they draw on blue paper, &c. It is found in pieces from two to ten feet long, and from four inches to twenty in breadth, generally flat, but somewhat rising in the middle, and thinner towards the edges, commonly lying in large quantities together. While in the earth, it is moist and flaky: but being dried, it becomes considerably hard and very light; but always breaks in some particular direction; and if attentively examined when fresh broken, appears of a striated texture. To the touch it is soft and smooth, stains very freely, and by virtue of its smoothness makes very neat marks. It is easily reduced into an impalpable soft powder without any diminution of its blackness. In this state it mixes easily with oil into a smooth paste; and being diffused through water, it slowly settles in a black slimy or muddy form; properties which make its use very convenient to the painters both in oil and water colours. It appears to be an earth quite different from common chalk, and rather of the slaty bituminous kind. In the fire it becomes white with a reddish cast, and very friable, retaining its flaky structure, and looking much like the white flaky masses which some sorts of pit-coal leave in burning. Neither the chalk nor these ashes are at all affected by acids.

The colour-shops are supplied with this earth from Italy or Germany; though some parts of England afford substances nearly, if not entirely, of the same quality, and which are found to be equally serviceable both for marking and as black paints. Such particularly is the black earth called *killoo*, said by Dr Merret in his *Pinax Rerum Britannicarum* to be found in Lancashire; and by Mr Da Costa, in his history of fossils,

to be plentiful near the top of Cay-Avon, an high hill in Merionethshire.

Red CHALK, an earth much used by painters and artificers, and common in the colour-shops. It is properly an indurated clayey ochre; and is dug in Germany, Italy, Spain, and France, but in greatest quantity in Flanders. It is of a fine, even, and firm texture; very heavy, and very hard; of a pale red on the outside, but of a deep dusky chocolate colour within. It adheres firmly to the tongue, is perfectly insipid to the taste, and makes no effervescence with acids.

CHALK-Land. Barley and wheat will succeed very well on the better sort of chalky land, and oats generally do well on any kind of it. The natural produce of this sort of land in weeds, is that sort of small vetch called the *tine-tare*, with poppies, may-weed, &c. Sainfoin and hop-clover will generally succeed tolerably well on these lands; and, where they are of the better sort, the great clover will do. The best manure is dung, old rags, and the sheep-dung left after folding them.

CHALK-Stones, in medicine, signify the concretions of calcareous matter in the hands and feet of people violently afflicted with the gout. Leeuwenhoek has been at the pains of examining these by the microscope. He divides them into three parts. The first is composed of various small parcels of matter looking like white grains of sand; this is harder and drier, and also whiter, than the rest. When examined with large magnifiers, these are found to be composed of oblong particles laid closely and evenly together: though the whole small stones are opaque, these component parts of them are pellucid, and resemble pieces of horse-hair cut short, only that they are somewhat pointed at both ends. These are so extremely thin, that Mr Leeuwenhoek computes that 1000 of them placed together would not amount to the size of one hair of our heads. The whole stones in this harder part of the chalk are not composed of these particles, but there are confusedly thrown in among them some broken parts of other substances, and in a few places some globules of blood and small remains of other juices. The second kind of chalky matter is less hard and less white than the former, and is composed of fragments or irregular parts of those oblong bodies which compose the first or hardest kind, and these are mixed among tough and clear matter, interspersed with the small broken globules of blood discoverable in the former, but in much greater quantity. The third kind appears red to the naked eye; and, when examined with glasses, is found to be a more tough and clammy white matter, in which a great number of globules of blood are interspersed; these give it the red appearance it has.

CHALLENGE, a cartel or invitation to a duel or other combat*. A challenge either by word or letter, or to be the bearer of such a challenge, is punishable by fine and imprisonment on indictment or information. See *Duels*.

CHALLENGE, among hunters. When hounds or beagles, at first finding the scent of their game, presently open and cry, they are said to challenge.

CHALLENGE, in the law of England, is an exception made to jurors†; and is either in civil or criminal cases. † See the article *Trial*.

I. In

Chalk, Challenge.

Challenge.

I. In *civil* cases challenges are of two sorts; challenges to the *array*, and challenges to the *poll*.

1. Challenges to the array are at once an exception to the whole panel, in which the jury are arrayed, or set in order by the sheriff in his return; and they may be made upon account of partiality or some default in the sheriff or his under officer who arrayed the panel. Also, though there be no personal objection against the sheriff, yet if he arrays the panel at the nomination, or under the direction of either party, this is good cause of challenge to the array. Formerly, if a lord of parliament had a cause to be tried, and no knight was returned upon the jury, it was a cause of challenge to the array: also by the policy of the ancient law, the jury was to come *de vicineto*, from the neighbourhood of the vill or place where the cause of action was laid in the declaration: and therefore some of the jury were obliged to be returned from the hundred in which such vill lay; and, if none were returned, the array might be challenged from defect of hundreders. For, living in the neighbourhood, these were supposed to know beforehand the characters of the parties and witnesses; and therefore they better knew what credit to give to the facts alleged in evidence. But this convenience was overbalanced by another very natural and almost unavoidable inconvenience; that jurors coming out of the immediate neighbourhood, would be apt to intermix their prejudices and partialities in the trial of right. And this the law was so sensible of, that it for a long time has been gradually relinquishing this practice; the number of necessary hundreders in the whole panel, which in the reign of Edward III. were constantly six, being in the time of Fortescue reduced to four; afterwards by statute 27 Eliz. c. 6. to two; and at length, by statute 4 and 5 Anne, c. 16. it was entirely abolished upon all civil actions, except upon penal statutes; and upon those also by the 24 Geo. II. c. 18. the jury being now only to come *de corpore comitatus*, from the body of the country at large, and not *de vicineto*, or from the particular neighbourhood. The array by the ancient law may also be challenged, if an alien be party to the suit, and, upon a rule obtained by his motion to the court for a jury *de medietate lingue*, such a one be not returned by the sheriff pursuant to the statute 28 Edward III. c. 13. enforced by 8 Hen. VI. c. 29. which enacts, that where either party is an alien born, the jury shall be one half denizens and the other aliens (if so many be forthcoming in the place), for the more impartial trial: A privilege indulged to strangers in no other country in the world; but which is as ancient in England as the time of King Ethelred, in whose statute *de monticulis Wallie* (then aliens to the crown of England), c. 3. it is ordained, that “*duodeni legales homines, quorum sex Walli et sex Angli erunt, Anglis et Wallis jus dicunto.*”

2. Challenges to the polls, *in capita*, are exceptions to particular jurors; and seem to answer the *recusatio judicis* in the civil and canon laws; by the constitutions of which, a judge might be refused upon any suspicion of partiality. By the laws of England also, in the times of Bracton and Fleta, a judge might be refused for good cause; but now the law is otherwise, and it is held that judges or justices cannot be challen-

ged. For the law will not suppose a possibility of bias or favour in a judge who is already sworn to administer impartial justice, and whose authority greatly depends on that presumption and idea. And, should the fact at any time prove flagrantly such, as the delicacy of the law will not presume beforehand, there is no doubt but that such misbehaviour would draw down a heavy censure from those to whom the judge is accountable for his conduct. But challenges to the polls of the jury (who are judges of fact) are reduced to four heads by Sir Edward Coke: *propter honoris respectum; propter defectum; propter affectum; and propter delictum.* 1. *Propter honoris respectum*; as, if a lord of parliament be impanelled on a jury, he may be challenged by either party, or he may challenge himself. 2. *Propter defectum*; as, if a jurymen be an alien born, this is defect of birth; if he be a slave or bondman, this is defect of liberty, and he cannot be a *liber et legalis homo*. Under the word *homo* also, though a name common to both sexes, the female is however excluded, *propter defectum sexus*: except when a widow feigns herself with child in order to exclude the next heir, and a supposititious birth is suspected to be intended; then, upon the writ *de ventre inspiciendo*, a jury of women is to be impanelled to try the question whether with child or not. But the principal deficiency is defect of estate sufficient to qualify him to be a juror, which depends upon a variety of statutes*. 3. Jurors may be challenged *propter affectum*, for suspicion of bias or partiality. This may be either a principal challenge, or to the favour. A principal challenge is such, where the cause assigned carries with it, *prima facie*, evident marks of suspicion either of malice or favour: as, that a juror is of kin to either party within the ninth degree; that he has an interest in the cause; that there is an action depending between him and the party; that he has taken money for his verdict, &c. which, if true, cannot be overruled, for jurors must be *omni exceptione majores*. Challenges to the favour, are where the party hath no principal challenge; but objects only some probable circumstances of suspicion, as acquaintance, and the like; the validity of which must be left to the determination of *triers*, whose office is to decide whether the juror be favourable or unfavourable. 4. Challenges *propter delictum*, are for some crime or misdemeanour that affects the juror's credit, and renders him infamous: As for a conviction of treason, felony, perjury, or conspiracy; or if, for some infamous offence, he hath received judgment of the pillory or the like.

II. In *criminal* cases, challenges may be made either on the part of the king, or on that of the prisoner; and either to the whole array, or to the separate polls, for the very same reasons that they may be in civil causes. For it is here at least as necessary as there, that the sheriff or returning officer be totally indifferent; that, where an alien is indicted, the jury should be *de medietate*, or half foreigners, if so many are found in the place (which does not indeed hold in treasons, aliens being very improper judges of the breach of allegiance; nor yet in the case of Egyptians under the statute 22 Hen. VIII. c. 10.); that on every pannel there should be a competent number of hundreders; and that the particular jurors should be *omni exceptione majores*, not liable to objections either *propter honoris respectum*,

Challenge.

* See Blackstone's Com. III. 362.

Challenge, *speculum, propter defectum, propter affectum, or propter delictum.*
Challon

Challenges on any of the foregoing accounts are styled challenges *for cause*; which may be without stint in both civil and criminal trials. But in criminal cases, or at least in capital ones, there is, *in favorem vite*, allowed to the prisoner an arbitrary and capricious species of challenge to a certain number of jurors, without showing any cause at all; which is called a peremptory challenge: a provision full of that tenderness and humanity to prisoners for which our laws are justly famous. This is grounded on two reasons: 1. As every one must be sensible what sudden impressions and unaccountable prejudices we are apt to conceive upon the bare looks and gestures of another; and how necessary it is, that a prisoner, when put to defend his life, should have a good opinion of his jury, the want of which might totally disconcert him; the law wills not that he should be tried by any one man against whom he has conceived a prejudice even without being able to assign a reason for such his dislike. 2. Because upon challenges for cause shown, if the reason assigned prove insufficient to set aside the juror, perhaps the bare questioning his indifference may sometimes provoke a resentment; to prevent all ill consequences from which, the prisoner is still at liberty, if he pleases, peremptorily to set him aside.

This privilege of peremptory challenges, though granted to the prisoner, is denied to the king by the statute 33 Edward I. stat. 4. which enacts, that the king shall challenge no jurors without assigning a cause certain to be tried and approved by the court. However, it is held that the king need not assign his cause of challenge till all the panel is gone through, and unless there cannot be a full jury without the persons so challenged. And then, and not sooner, the king's counsel must show the cause: otherwise the juror shall be sworn.

The peremptory challenges of the prisoner must, however, have some reasonable boundary; otherwise he might never be tried. This reasonable boundary is settled by the common law to the number of 35; that is, one under the number of three full juries. For the law judges, that 35 are fully sufficient to allow the most timorous man to challenge through mere caprice; and that he who peremptorily challenges a greater number, or three full juries, has no intention to be tried at all. And therefore it deals with one who peremptorily challenges above 35, and will not retract his challenge, as with one who stands mute or refuses his trial; by sentencing him to the *peine forte et dure* in felony, and by attainting him in treason. And so the law stands at this day with regard to treason of any kind. But by statute 22 Hen. VIII. c. 14. (which, with regard to felonies, stands unrepealed), no person arraigned for felony can be admitted to make more than 20 peremptory challenges.

CHALLON-SUR-SAONE, an ancient town of France, in Burgundy, and capital of the Chalonnois, with a citadel and bishop's see. It is seated on the river Saone, in E. Long. 5. 7. N. Lat. 46. 47.

CHALLONS-SUR-MARNE, a large episcopal town of France, in Champagne. It carries on a considerable trade in shalloons, and other woollen stuffs. It is seated

between two fine meadows on the rivers Marne, Mau, and Nau, in E. Long. 4. 37. N. Lat. 48. 57.

CHALONER (Sir Thomas), a statesman, soldier, and poet, descended from a good family in Denbigh in Wales, was born at London about the year 1515. Having been educated in both universities, but chiefly at Cambridge, he was introduced at the court of Henry VIII. who sent him abroad in the retinue of Sir Henry Knevet ambassador to Charles V. and he had the honour to attend that monarch on his fatal expedition against Algiers in 1541. Soon after the fleet left that place, he was shipwrecked on the coast of Barbary in a very dark night: and having exhausted his strength by swimming, he chanced to strike his head against a cable, which he had the presence of mind to catch hold of with his teeth; and, with the loss of several of them, was drawn up by it into the ship to which he belonged. Mr Chaloner returned soon after to England, and was appointed first clerk of the council, which office he held during the rest of that reign. On the accession of Edward VI. he became a favourite of the Duke of Somerset, whom he attended to Scotland, and was knighted by that nobleman after the battle of Musselburgh, in 1547. The protector's fall put a stop to Sir Thomas Chaloner's expectations, and involved him in difficulties. During the reign of queen Mary, being a determined protestant, he was in some danger; but having many powerful friends, he had the good fortune to escape. On the accession of queen Elizabeth, he appeared again at Court; and was so immediately distinguished by her Majesty, that she appointed him ambassador to the emperor Ferdinand I. being the first ambassador she nominated. His commission was of great importance; and the queen was so well satisfied with his conduct, that, soon after his return, she sent him in the same capacity to Spain: but Sir Thomas was by no means satisfied with this instance of her majesty's confidence: the courts of England and Spain being at this time extremely dissatisfied with each other, he foresaw that his situation would be very disagreeable; and so it proved; but Elizabeth must be obeyed. He embarked for Spain in 1561, and returned to London in 1564, in consequence of a request to his sovereign, in an elegy written in imitation of Ovid. After his return, he resided in a house built by himself in Clerkenwell-close, where he died in the year 1565, and was buried in St Paul's. Sir William Cecil assisted as chief mourner at his funeral.

So various were the talents of Sir Thomas Chaloner, that he excelled in every thing to which he applied himself. He made a considerable figure as a poet. His poetical works were published by William Malim, master of St Paul's school, in 1579. His capital work was that "Of restoring the English republic, in ten books," which he wrote when he was ambassador in Spain. It is remarkable, that this great man, who knew how to transact as well as write upon the most important affairs of states and kingdoms, could descend to compose a *dictionary for children*, and to translate from the Latin a book *Of the office of Servants*, merely for the utility of the subjects.

CHALONER (Sir Thomas) the younger, though inconsiderable as an author, deserves to be recorded as a skilful naturalist, in an age wherein natural history was

Chaloner
||
Cham.

very little understood in this or any other country; and particularly as the founder of the alum-works in Yorkshire, which have since proved so exceedingly advantageous to the commerce of this kingdom. He was the only son of Sir Thomas Chaloner mentioned in the last article, and was born in the year 1559. Being very young at the time of his father's death, the lord treasurer Burleigh taking charge of his education, sent him to St Paul's school, and afterwards to Magdalen college in Oxford, where, like his father, he discovered extraordinary talents for Latin and English poetry. About the year 1580, he made the tour of Europe, and returned to England before 1584; for, in that year, we find him a frequent attendant in the court of queen Elizabeth. About this time he married the daughter of Sir William Fleetwood, recorder of London. In 1591 he was knighted; and, some time after, discovered the alum-mines on his estate at Gisborough, near the river Tees in Yorkshire (A).

Towards the latter end of the queen's reign, Sir Thomas visited Scotland; and returning to England in the retinue of king James I. found such favour in the sight of his majesty, that he was immediately appointed governor to prince Henry, whom he constantly attended, and, when his royal pupil visited Oxford, was honoured with the degree of master of arts. How he was employed after the death of the prince is not known. Some years before that event, he married a second wife, the daughter of Mr William Blount of London, by whom he had some children. He died in the year 1615, and was buried at Chiswick in Middlesex. His eldest son William was created a baronet in the 18th of James *anno* 1620. The title was extinct in 1681. He wrote, 1. *Dedication to Lord Burleigh of his father's poetical works*, dated 1579. 2. *The virtue of nitre, wherein is declared the sundry cures by the same effected*. Lond. 1584, 4to.

CHALYBEAT, in medicine, an appellation given to any liquid, as wine or water, impregnated with particles of iron or steel. See MINERAL WATERS.

CHALYBES (anc. geog.), an ancient people of the Hither Asia. Their situation is differently assigned; Strabo placing them in Paphlagonia, to the east of Synope; Apollonius Rhodus and Stephanus, on the east of the Thermodon, in Pontus; called *Halyzones* by Homer. They either gave their name to, or took it from, their iron manufactures, (Xenophon, Val. Flaccus), their only support, their soil being barren and ungrateful, (Dionysius Periegetes).

CHAM, or KHAN, the title given to the sovereign princes of Tartary.

The word, in the Persian, signifies *mighty lord*; in the Slavonic, *emperor*. Sperlingius, in his Dissertation on the Danish term of *Majesty*, *koning*, *king*, thinks the Tartarian *cham* may be well derived from it; add-
N^o 68.

ing, that in the north they say *kan*, *konnen*, *konge*, *koning*, &c. The term *cham* is also applied, among the Persians, to the great lords of the court, and the governors of provinces.

CHAM, in geography, a town of the Bavarian palatinate, situated on a river of the same name, about 25 miles north-east of Ratisbon; E. Long. 13. N. Lat. 49. 15.

CHAMA, in zoology, a genus of shell-fish belonging to the order of vermes testaceæ. The shell is thick, and has two valves; it is an animal of the oyster kind. Linnæus enumerates 14 species, principally distinguished by the figure of their shells.

CHAMADE, in war, a certain beat of a drum, or sound of a trumpet, which is given the enemy as a signal to inform them of some proposition to be made to the commander, either to capitulate, to have leave to bury their dead, make a truce, or the like.—Menage derives the word from the Italian *chiamata*, of *clamar* to "cry."

CHAMÆDRYS, in botany. See VERONICA.

CHAMÆLEON, in zoology, the trivial name of a species of LACERTA.

CHAMÆPITYS, in botany. See TEUCRIUM.

CHAMÆROPS, in botany: A genus of the natural order of palmæ. The hermaphrodite calyx is tripartite; the corolla tripetalous; there are six stamens, three pistils, and three monospermous plums. The male, in a distinct plant, the same as the hermaphrodite. There are two species, the most remarkable of which is the *glabra*, a native of the West Indies, and warm parts of America, also of the corresponding latitudes of Asia and Africa. It never rises with a tall stem; but when the plants are old, their leaves are five or six feet long, and upwards of two feet broad; these spread open like a fan, having many foldings, and at the top are deeply divided like the fingers of a hand. This plant the Americans call *thatcb*, from the use to which the leaves are applied.—Under the name of *palmetto*, however, Mr Adanson describes a species of palm which grows naturally at Senegal, whose trunk rises from 50 to 60 feet in height: from the upper end of the trunk issues a bundle of leaves, which, in turning off, form a round head; each leaf represents a fan of five or six feet in expansion, supported by a tail of the same length. Of these trees, some produce male flowers, which are consequently barren; others are female, and loaded with fruit, which succeed each other uninterruptedly almost the whole year round. The fruit of the large palmettos, Mr Adanson affirms to be of the bigness of an ordinary melon, but rounder: it is enveloped in two skins as tough as leather, and as thick as strong parchment; within the fruit is yellowish, and full of filaments fastened to three large kernels in the middle. The negroes are very fond of this fruit,
which,

Chama
||
Chamæ-
rops.

(A) Sir Thomas, during his residence in Italy, being particularly fond of natural history, spent some time at Puzzoli, where he was very attentive to the art of producing alum. This attention proved infinitely serviceable to his country, though of no great benefit to himself or his family, his attempt being attended with much difficulty and expence. It was begun about the year 1600, in the reign of queen Elizabeth; but was not brought to any degree of perfection till some time in the reign of Charles I. by the assistance of one Ruffel a Walloon, and two other workmen brought from the alum-works at Rochelle. By one of the arbitrary acts of Charles, it was then deemed a mine-royal, and granted to Sir Paul Pindar. The long parliament adjudged it a monopoly, and justly restored it to the original proprietors.

Chamanim which, when baked under the ashes, is said to taste like a quince.

Chamber.

The little palmetto may be easily raised in this country from seeds brought from America; but, as the plants are tender, they must be constantly kept in a bark-stove.

CHAMANIM, in the Jewish antiquities, is the Hebrew name for that which the Greeks call *Pyreia* or *Pyraeria*; and St Jerom in Leviticus has translated *Simulachra*, in Isaiah, *delubra*. These *chamanim* were, according to Rabbi Solomon, idols exposed to the sun upon the tops of houses. Abenezra says they were portable chapels or temples made in the form of chariots, in honour of the sun. What the Greeks call *Pyreia*, were temples consecrated to the sun and fire, wherein a perpetual fire was kept up. They were built upon eminences; and were large inclosures without covering, where the sun was worshipped. The *Guebres*, or worshippers of fire, in Persia and the East Indies, have still these *Pyreia*. The word *chamanim* is derived from *Chaman*, which signifies to warm, or burn.

CHAMARIM, a word which occurs in several places of the Hebrew bible, and is generally translated the *priests of the idols*, or the *priests clothed in black*, because *chamar* signifies "black," or "blackness." St Jerom, in the second book of Kings, renders it *aruspices*. In Hosea and Zephania, he translates it *editui* or church-wardens. But the best commentators are of opinion, that by this word we are to understand the priests of the false gods, and in particular the worshippers of fire; because they were, as they say, dressed in black; or perhaps the Hebrews gave them this name in derision, because, as they were continually employed in taking care about the fuel, and keeping up the fire, they were always as black as smiths or colliers. We find priests, among those of Isis, called *melanephori*, that is to say, that wear black; but whether this may be by reason of their dressing in black, or whether it were because they wore a certain shining black veil in the processions of this goddess, is not certain. *Cammar*, in Arabic, signifies the "moon." Isis is the same deity. Grotius thinks the Roman priests, called *camilli*, came from the Hebrew *chamarim*. Those among the heathens who sacrificed to the infernal gods were dressed in black.

CHAMBER, in building, a member of a lodging, or piece of an apartment, ordinarily intended for sleeping in; and called by the Latins *cubiculum*. The word comes from the Latin *camera*; and that, according to *Nicod*, from the Greek *καμαρα*, vault or curve; the term *chamber* being originally confined to places arched over.

A complete apartment is to consist of a hall, anti-chamber, *chamber*, and cabinet.

Privy-CHAMBER. Gentlemen of the privy-chamber, are servants of the king, who are to wait and attend on him and the queen at court, in their diversions, &c. Their number is forty-eight, under the lord-chamberlain, twelve of whom are in quarterly waiting, and two of these lie in the privy-chamber.

In the absence of the lord-chamberlain, or vice-chamberlain, they execute the king's orders: at coronations, two of them personate the dukes of Aquitaine and Normandy; and six of them, appointed by the

VOL. IV. Part I.

lord-chamberlain, attend ambassadors from crowned heads to their audiences, and in public entries. The gentlemen of the privy-chamber were instituted by Henry VII.

CHAMBER, in policy, the place where certain assemblies are held, also the assemblies themselves. Of these some are established for the administration of justice, others for commercial affairs.

Of the first kind are, 1. Star-chamber, so called, because the roof was painted with stars; the authority, power, and jurisdiction of which, are absolutely abolished by the statute 17 Car. I. 2. Imperial chamber of Spire, the supreme court of judicatory in the empire, erected by Maximilian I. This chamber has a right of judging by appeal; and is the last resort of all civil affairs of the states and subjects of the empire, in the same manner as the aulic council of Vienna. Nevertheless it is restrained in several cases: it takes no notice of matrimonial causes, these being left to the pope; nor of criminal causes, which either belong to particular princes or towns in their respective territories, or are cognizable by all the states of the empire in a diet. By the treaty of Osnaburg, in 1648, fifty assessors were appointed for this chamber, whereof 24 were to be Protestants, and 26 Catholics; besides five presidents, two of them Protestants, and the rest Catholics. 3. Chamber accounts, a sovereign court in France, where accounts are rendered of all the king's revenues, inventories, and avowals thereof registered; oaths of fidelity taken, and other things relating to the finances transacted. There are nine in France, that of Paris is the chief; it registers proclamations, treaties of peace, naturalizations, titles of nobility, &c. All the members wear long black gowns of velvet, of satin, or damask, according to their places. 4. Ecclesiastical chambers in France, which judge by appeal of differences about collecting the tythes. 5. Chamber of audience, or grand chamber, a jurisdiction in each parliament of France, the counsellors of which are called *jugeurs*, or judges, as those of the chamber of inquests are called *rapporteurs*, reporters of processes by writing. 6. Chamber of the edict, or miparty, a court established by virtue of the edict of pacification in favour of those of the reformed religion. This chamber is now suppressed. 7. Apostolical chamber of Rome, that wherein affairs relating to the revenues of the church and the pope are transacted. This council consists of the cardinal-camerlingo, the governor of the rota, a treasurer, an auditor, a president, one advocate-general, a solicitor-general, a commissary, and 12 clerks. 8. Chamber of London, an apartment in Guildhall, where the city money is deposited.

Of the last sort are, the chambers of commerce; the chambers of assurance; and the royal or syndical chamber of booksellers in France.

1. The chamber of commerce is an assembly of merchants and traders, where the affairs relating to trade are treated of. There are several established in most of the chief cities of France; and in our own country, we have lately seen chambers of this kind erected, particularly in London, Edinburgh, and Glasgow. 2. Chamber of assurance in France, denotes a society of merchants and others for carrying on the business of insuring: but in Holland, it signifies a court of justice, where causes relating to insurances are tried.

S s

3. Cham-

Chamber,
Chamber-
lain.

3. Chamber of booksellers in Paris, an assembly consisting of a syndic and assistants, elected by four delegates from the printers, and twelve from the booksellers, to visit the books imported from abroad, and to search the houses of sellers of marbled paper, printers, and dealers in printed paper for hangings, who are prohibited from keeping any letters proper for printing-books. In the visitation of books, which ought to be performed by three persons at least from among the syndic and assistants, all libels against the honour of God and the welfare of the state, and all books printed either within or without the kingdom in breach of their regulations and privileges, are stopt, even with the merchandises that may happen to be in the bales with such libels or other prohibited books. The days appointed for this chamber to meet, are Tuesdays and Fridays, at two o'clock in the afternoon.

CHAMBER, in military affairs. 1. Powder-chamber, or bomb-chamber; a place sunk under ground for holding the powder, or bombs, where they may be out of danger, and secured from the rain. 2. Chamber of a mine; the place, most commonly of a cubical form, where the powder is confined. 3. Chamber of a mortar; that part of the chase, much narrower than the rest of the cylinder, where the powder lies. It is of different forms; sometimes like a reversed cone; sometimes globular, with a neck for its communication with the cylinder, whence it is called a bottled chamber; but most commonly cylindrical, that being the form which is found by experience to carry the ball to the greatest distance.

CHAMBERLAIN, an officer charged with the management and direction of a chamber. See CHAMBER, in policy.

There are almost as many kinds of chamberlains as chambers, the principal whereof are as follows.

Lord CHAMBERLAIN of Great Britain, the sixth great officer of the crown; to whom belongs livery and lodging in the king's court; and there are certain fees due to him from each archbishop or bishop when they perform their homage to the king, and from all peers at their creation or doing their homage. At the coronation of every king, he is to have forty ells of crimson velvet for his own robes. This officer, on the coronation-day, is to bring the king his shirt, coif, and wearing clothes; and after the king is dressed, he claims his bed, and all the furniture of his chamber, for his fees: he also carries, at the coronation, the coif, gloves, and linen, to be used by the king on that occasion; also the sword and scabbard, the gold to be offered by the king, and the robes-royal and crown: he dresses and undresses the king on that day, waits on him before and after dinner, &c. To this officer belongs the care of providing all things in the house of lords, in the time of parliament; to him also belongs the government of the palace of Westminster: he disposes likewise of the sword of state, to be carried before the king, to what lord he pleases.

The great chamberlain of Scotland was ranked by King Malcolm as the third great officer of the crown, and was called *Camerarius Domini Regis*. Before there was a treasurer appointed, it was his duty to collect the revenue of the crown, and he disbursed the money necessary for the king's expences, and the maintenance

of the king's household. From the time that a treasurer was appointed, his province was limited to the boroughs throughout the kingdom, where he was a sort of justice-general, as he had a power for judging of all crimes committed within the borough, and of the crime of forestalling. He was to hold chamberlain-ayres every year. He was supreme judge; nor could any of his decrees be questioned by any inferior judicatory. His sentences were put in execution by the magistrates of the boroughs. He also regulated the prices of provisions within the borough, and the fees of the workmen in the mint-house. His salary was only L. 200 a-year. The smallness of his salary, and his great powers, had no doubt been the causes of much oppression in this officer, and the chamberlain-ayre was called rather a legal robbery than a court of justice; and when the combined lords seized king James VI. August 24, 1582, and carried him to Ruthven Castle, they issued a proclamation in the king's name, discharging the chamberlain-ayres to be kept. The chamberlain had great fees arising from the profits of escheats, fines, tolls, and customs. This office was granted heritably to the family of Stuart, duke of Lenox; and when their male line failed, king Charles II. conferred it in like manner upon his natural son, whom he created duke of Monmouth, and on his forfeiture it went to the duke of Lenox; but that family surrendered the office to the crown in 1703.

Lord CHAMBERLAIN of the Household, an officer who has the oversight and direction of all officers belonging to the king's chambers, except the precinct of the king's bed-chamber.

He has the oversight of the officers of the wardrobe at all his majesty's houses, and of the removing wardrobes, or of beds, tents, revels, music, comedians, hunting, messengers, &c. retained in the king's service. He moreover has the oversight and direction of the serjeants at arms, of all physicians, apothecaries, surgeons, barbers, the king's chaplains, &c. and administers the oath to all officers above stairs.

Other chamberlains are those of the king's court of exchequer, of North Wales, of Chester, of the city of London, &c. in which cases this officer is generally the receiver of all rents and revenues belonging to the place whereof he is chamberlain.

In the exchequer there are two chamberlains, who keep a controlment of the pells of receipts and exitus, and have certain keys of the treasury, records, &c.

CHAMBERLAIN of London keeps the city money, which is laid up in the chamber of London: he also presides over the affairs of masters and apprentices, and makes free of the city, &c.

His office lasts only a year; but the custom usually obtains to re-chuse the same person, unless charged with any misdemeanor in his office.

CHAMBERLAYNE (Edward), descended from an ancient family, was born in Gloucestershire 1616, and made the tour of Europe during the distractions of the civil war. After the restoration, he went as secretary with the earl of Carlisle, who carried the order of the Garter to the king of Sweden; was appointed tutor to the duke of Grafton, natural son of Charles II. and was afterwards pitched on to instruct prince George of Denmark in the English tongue. He died in 1703, and was buried in a vault in Chelsea church.

Chambers.

church-yard: his monumental inscription mentions six books of his writing; and that he was desirous of doing service to posterity, that he ordered some copies of his books to be covered with wax, and buried with him. That work by which he is best known, is his *Anglie Notitia, or the present state of England*, which has been often since printed.

CHAMBERLAYNE (John), son to the authors of *The Present State of England*, and continuator of that useful work, was admitted into Trinity College, Oxford, 1685; but it doth not appear that he took any degree. Beside the *Continuation* just mentioned, he was author of "Dissertations historical, critical, theological, and moral, on the most memorable events of the Old and New Testaments, with Chronological Tables;" one vol. folio; and translated a variety of works from the French, Dutch, and other languages. He likewise was F. R. S. and communicated some pieces, inserted in the *Philosophical Transactions*. It was said of him that he understood sixteen languages; but it is certain that he was master of the Greek, Latin, French, High and Low Dutch, Portuguese, and Italian. Though he was qualified for employment, he had none but that of Gentleman-Usher to George Prince of Denmark. After a useful and well-spent life, he died in the year 1724. He was a very pious and good man, and earnest in promoting the advancement of religion, and the interest of true Christianity; for which purpose he kept a large correspondence abroad.

CHAMBERRY, a considerable and populous town of Italy, in Savoy, with a castle. It is capital of the duchy, and well built, but has no fortifications. It is watered by several streams, which have their sources in St Martin's-hill, and run through several of the streets. There are piazzas under most part of the houses, where people may walk dry in the worst weather. It hath large and handsome suburbs; and in the centre of the town is the royal palace. The parliament meet here, which is composed of four presidents, and a pretty large number of senators, being the supreme tribunal of the whole duchy. The principal church is St Leger, and the Jesuits college is the most magnificent of all the monasteries. E. Long. 5. 50. N. Lat. 45. 35.

CHAMBERS (David), a Scots historian, priest, and lawyer, was born in the shire of Ross, about the year 1530, and educated in the university of Aberdeen. From thence he went to France and Italy, where he continued sometime, particularly at Boulogne, where, in 1556, he was a pupil of Marianus Sozenus.

After his return to Scotland, he was appointed, by queen Mary, parson of Suddy and chancellor of Ross. He was soon after employed in digesting the laws of Scotland, and was principally concerned in publishing the acts of parliament of that kingdom by authority in 1566. He was also appointed one of the lords of session, and continued her majesty's faithful servant till her declining fortune obliged her adherents to seek for refuge in other kingdoms. Chambers went first to Spain, where he was graciously received by king Philip; and thence he travelled to Paris, where he was no less kindly received by Charles IX. of that kingdom, to whom, in 1572, he presented his history of Scotland, &c. He died at Paris in the year 1592, much regretted (says Mackenzie) by all who knew

him. His writings were chiefly calculated to assist his royal mistress, and to extol the wisdom of the Scots nation.

CHAMBERS (Ephraim), author of the scientific Dictionary which goes under his name, was born at Milton, in the county of Westmoreland. His parents were dissenters of the Presbyterian persuasion; and his education no other than that common one which is intended to qualify a youth for trade and commerce. When he became of a proper age, he was put apprentice to Mr Senex the globe-maker, a business which is connected with literature, and especially with astronomy and geography. It was during Mr Chambers's residence with this skilful mechanic, that he contracted that taste for science and learning which accompanied him through life, and directed all his pursuits. It was even at this time that he formed the design of his grand work, the "Cyclopædia;" and some of the first articles of it were written behind the counter. Having conceived the idea of so great an undertaking, he justly concluded that the execution of it would not consist with the avocations of trade; and therefore he quitted Mr Senex, and took chambers at Gray's-Inn, where he chiefly resided during the rest of his days. The first edition of the *Cyclopædia*, which was the result of many years intense application, appeared in 1728, in two vols. fol. It was published by subscription, the price being 4l. 4s. and the list of subscribers was very respectable. The dedication, which was to the king, is dated October 15. 1727. The reputation that Mr Chambers acquired by his execution of this undertaking, procured him the honour of being elected F. R. S. Nov. 6. 1729. In less than ten years time, a second edition became necessary; which accordingly was printed, with corrections and additions, in 1738; and was followed by a third the very next year.

Although the *Cyclopædia* was the grand business of Mr Chambers's life, and may be regarded as almost the sole foundation of his fame, his attention was not wholly confined to this undertaking. He was concerned in a periodical publication, intitled, "The Literary Magazine," which was begun in 1735. In this work he wrote a variety of articles, and particularly a review of Morgan's "Moral Philosopher." He was engaged, likewise, in conjunction with Mr John Martyn, F. R. S. and professor of botany at Cambridge, in preparing for the press a translation and abridgment of the "Philosophical History and Memoirs of the Royal Academy of Sciences at Paris, or an Abridgment of all the Papers relating to Natural Philosophy which have been published by the Members of that illustrious Society." This undertaking, when completed, was comprised in five volumes 8vo, which did not appear till 1742, some time after our author's decease, when they were published in the joint names of Mr Martyn and Mr Chambers. Mr Martyn, in a subsequent publication, hath passed a severe censure, upon the share which his fellow-labourer had in the abridgment of the Parisian papers. The only work besides, that we find ascribed to Mr Chambers, is a translation of the *Jesuit's Perspective*, from the French; which was printed in 4to, and hath gone through several editions. Mr Chambers's close and unremitting attention to his studies at length impaired his

Chambers
||
Chamos.

health, and obliged him occasionally to take a lodging at Canonbury-house, Islington. This not having greatly contributed to his recovery, he made an excursion to the south of France, but did not reap that benefit from it which he had himself hoped, and his friends wished. Returning to England, he died at Canonbury-house, and was buried at Westminster; where the following inscription, written by himself, is placed on the north side of the cloysters of the Abbey:

Multis pervulgatus,
Paucis notus;
Qui vitam, inter lucem & umbram,
Nec eruditus, nec idiota,
Literis deditus, transegit; sed ut homo
Qui humani nihil a se alienum putat.
Vita simul, & laboribus functus,
Hic requiescere voluit,
EPHRAIM CHAMBERS, R. S. S.
Obiit xv Maii, MDCCXL.

After the author's death, two more editions of his Cyclopædia were published. The proprietors afterwards procured a supplement to be compiled, which extended to two volumes more: And in the year 1778 began to be published in weekly numbers, an edition of both, improved, and incorporated into one alphabet, by Dr Rees, which has been lately completed in four volumes folio, and forms a very valuable work.

CHAMBRE (Martin Cureau de la), physician in ordinary to the French king, was distinguished by his knowledge in medicine, philosophy, and polite learning. He was born at Mons; and was received into the French academy in 1635, and afterwards into the academy of sciences. He wrote a great number of works, the principal of which are, 1. The characters of the passions. 2. The art of knowing men. 3. On the knowledge of beasts, &c. He died at Paris in 1669.

CHAMELEON. See LACERTA.

CHAMFERING, in architecture, a phrase used for cutting any thing aslope on the under side.

CHAMIER (Daniel), an eminent protestant divine, born in Dauphine. He was many years preacher at Montellimart; from whence he went in 1612 to Montaubon, to be professor of divinity in that city, and was killed by a cannon-ball during the siege in 1621. The most considerable of his works is his *Pan-stratia Catholica*, or "Wars of the Lord," in four volumes folio; in which he treats very learnedly of the controversies between the Protestants and Roman Catholics.

CHAMOIS, or CHAMOIS-GOAT, in zoology. See CAPRA.

CHAMOMILE. See ANTHEMIS.

CHAMOS, or CHEMOSH, the idol or god of the Moabites.

The name of *chamos* comes from a root which, in Arabic, signifies to *make haste*; for which reason many believe *chamos* to be the sun, whose precipitate course might well procure it the name of swift or speedy. Others have confounded *chamos* with the god *Hammon*, adored not only in Libya and Egypt, but also in Arabia, Ethiopia, and the Indies. Macrobius shows that *Hammon* was the sun; and the horns, with which he was represented, denoted his rays. Calmet is of opinion, that the god *Hamon*, and *Apollo Chomeus*, mentioned by Strabo and Ammianus Marcellinus, was

the very same as *chamos* or the sun. These deities *Chamouni* were worshipped in many of the eastern provinces. Some who go upon the resemblance of the Hebrew term *chamos*, to that of the Greek *comos*, have believed *chamos* to signify the god Bacchus the god of drunkenness, according to the signification of the Greek *comos*. St Jerom, and with him most other interpreters, take *Chamos* and *Peor* for the same deity. But it seems that *Baal-Peor* was the same as *Tammuz* or *Adonis*; so that *Chamos* must be the god whom the heathens call the Sun.

CHAMOUNI, one of the elevated valleys of the Alps, situated at the foot of Mount Blanc. See ALPS and BLANC.

The first strangers whom a curiosity to visit the glaciers drew to Chamouni (M. Saffure observes), certainly considered this valley as a den of robbers; for they came armed cap-a-pee, attended with a troop of domestics armed in the same manner; they would not venture into any house; they lived in tents which they had brought along with them; fires were kept burning, and centinels on guard the whole night over. It was in the year 1741 that the celebrated traveller Pogoek, and another English gentleman called Wyndham, undertook this interesting journey. It is remembered by the old men of Chamouni, and they still laugh at the fears of the travellers, and at their unnecessary precautions. For 20 or 25 years after this period, the journey was made but seldom, and then chiefly by Englishmen, who lodged with the curate: for, when I was there in 1760, and even for four or five years afterwards, there was no habitable house except one or two miserable inns, like those in villages that are little frequented. But now that this expedition has gradually become so fashionable, three large and good inns, which have been successively built, are hardly sufficient to contain the travellers that come during the summer from all quarters.

This concourse of strangers, and the money they leave behind them at Chamouni, have somewhat affected the ancient simplicity of the inhabitants, and even the purity of their manners. Nobody, however, has any thing to fear from them: the most inviolable fidelity is observed with respect to travellers; they are only exposed to a few importunate solicitations, and some small artifices, dictated by the extreme eagerness with which the inhabitants offer their services as guides.

The hope of obtaining this employment brings together, round a traveller, almost all the men in every village through which he passes, and makes him believe that there are a great many in the valley; but there are very few at Chamouni in summer. Curiosity, or the hope of making money, draws many to Paris and into Germany: besides, as the sheperds of Chamouni have the reputation of excelling in the making of cheese, they are in great request in the Tarentaise, in the valley of Aoste, and even at greater distances; and they receive there, for four or five months in summer, very considerable wages. Thus the labours of the field devolve almost entirely on the women, even such as in other countries fall solely on the men; as mowing, cutting of wood, and threshing: even the animals of the same sex are not spared, for the cows there are yoked in the plough.

Chamouni.

The only labours that belong exclusively to the men are the seeking for rock crystal, and the chace. Happily they are now less employed than formerly in the first of these occupations. I say happily, for many of them perished in this pursuit. The hope of enriching themselves quickly by the discovery of a cavern filled with fine crystals, was so powerful a motive, that they exposed themselves in the search to the most alarming dangers; and hardly a year passed without some of them perishing in the snows, or among the precipices.

The principal indication of the grottos, or crystal ovens, as they are here called, are veins of quartz, which appear on the outside of the rocks of granite, or of the laminated rock. These white veins are seen at a distance, and often at great heights, on vertical and inaccessible places. The adventurers endeavour to arrive at these, either by fabricating a road across the rocks, or by letting themselves down from above suspended by ropes. When they reach the place, they gently strike the rock; and if the stone returns a hollow sound, they endeavour to open it with a hammer, or to blow it up with powder. This is the principal method of searching: but young people, and even children, often go in quest of these crystals over the glaciers, where the rocks have lately fallen down. But whether they consider these mountains as nearly exhausted, or that the quantity of crystal found at Madagascar has too much lowered the price of this fossil, there are now but few people that go in search of it, and perhaps there is not a single person at Chamouni that makes it his only occupation. They go however occasionally, as to a party of pleasure.

But the chace of the Chamois goat, as dangerous, and perhaps more so than the seeking for crystal, still occupies many inhabitants of the mountains, and carries off, in the flower of their age, many men whose lives are most valuable to their families. And when we are informed how this chace is carried on, we will be astonished that a course of life, at once so laborious and perilous, should have irresistible attractions for those who have been accustomed to it.

The Chamois hunter generally sets out in the night, that he may reach by break of day the most elevated pastures where the goats come to feed, before they arrive. As soon as he discovers the place where he hopes to find them, he surveys it with his glass. If he finds none of them there, he proceeds always ascending: whenever he descends any, he endeavours to get above them, either by stealing along some gully, or getting behind some rock or eminence. When he is near enough to distinguish their horns, which is the mark by which he judges of the distance, he rests his piece on a rock, takes his aim with great composure, and rarely misses. This piece is a rifle-barrelled carabine, into which the ball is thrust, and these carabines often contain two charges, though they have but one barrel; the charges are put one above another, and are fired in succession. If he has wounded the chamois, he runs to his prey, and for security he hamstringing it; then he considers his way home: if the road is difficult, he skins the chamois, and leaves the carcase; but, if it is practicable, he throws the animal on his shoulders, and bears him to his village, though at a great distance, and often over frightful precipices: he feeds his family with the flesh, which is excellent, especially

when the creature is young, and he dries the skins for sale. Chamouni.

But if, as is the most common case, the vigilant chamois perceives the approach of the hunter, he immediately takes flight among the glaciers, through the snows, and over the most precipitous rocks. It is particularly difficult to get near these animals when there are several together; for then one of them, while the rest are feeding, stands as a centinel on the point of some rock that commands a view of the avenues leading to the pasture; and as soon as he perceives any object of alarm, he utters a sort of hiss, at which the others instantly gather round him to judge for themselves of the nature of the danger: if it is a wild beast, or a hunter, the most experienced puts himself at the head of the flock; and away they fly, ranged in a line, to the most inaccessible retreats.

It is here that the fatigues of the hunter begin: incited by his passion for the chace, he is insensible to danger; he passes over snows, without thinking of the horrid precipices they conceal; he intangles himself among the most dangerous paths, and bounds from rock to rock, without knowing how he is to return. Night often surprises him in the midst of his pursuit; but he does not for that reason abandon it; he hopes that the same cause will arrest the flight of the chamois, and that he will next morning overtake them. Thus he passes the night, not at the foot of a tree, like the hunter of the plain; not in a grotto, softly reclined on a bed of moss, but at the foot of a rock, and often on the bare points of shattered fragments, without the smallest shelter. There, all alone, without fire, without light, he draws from his bag a bit of cheese, with a morsel of oaten bread, which make his common food: bread so dry, that he is sometimes obliged to break it between two stones, or with the hatchet he carries with him to cut out steps in the ice. Having thus made his solitary and frugal repast, he puts a stone below his head for a pillow, and goes to sleep, dreaming on the rout which the chamois may have taken. But soon he is awakened by the freshness of the morning; he gets up, benumbed with cold; surveys the precipices which he must traverse in order to overtake his game; drinks a little brandy, of which he is always provided with a small portion, and sets out to encounter new dangers. Hunters sometimes remain in these solitudes for several days together, during which time their families, their unhappy wives in particular, experience a state of the most dreadful anxiety: they dare not go to rest for fear of seeing their husbands appear to them in a dream; for it is a received opinion in the country, that when a man has perished, either in the snow, or on some unknown rock, he appears by night to the person he held most dear, describes the place that proved fatal to him, and requests the performance of the last duties to his corpse.

"After this picture of the life which the chamois hunters lead, could one imagine that this chace would be the object of a passion absolutely unsupportable? I knew a well-made, handsome man, who had just married a beautiful woman:—'My grandfather, said he to me, lost his life in the chace; so did my father; and I am persuaded, that I too shall die in the same manner: this bag which I carry with me when I hunt I call my grave-cloaths, for I am sure I will.'"
Voyage dans les Alpes, par M. de Saussure, tom. iii.

will.

Chamouni. will have no other; yet if you should offer to make my fortune on condition of abandoning the chase of the chamois, I could not consent. I made some excursions on the Alps with this man: his strength and address were astonishing; but his temerity was greater than his strength; and I have heard, that, two years afterwards, he missed a step on the brink of a precipice, and met with the fate he had expected.

"The few who have grown old in this employment bear upon their faces the marks of the life they have led. A savage look, something in it haggard and wild, makes them be known in the midst of a crowd, even when they are not in their hunting drefs. And undoubtedly it is this ill look which makes some superstitious peasants believe that they are forcerers, that they have dealings with the devil in their solitudes, and that it is he who throws them down the rocks. What then can be the passionate inducement to this course of life? It is not avarice, at least it is not an avarice consistent with reason: the most beautiful chamois is never worth more to the person that kills it than a dozen of francs, even including the value of its flesh; and now that the number is so much diminished, the time lost before one can be taken is much more than its value. But it is the very dangers that attend the pursuit, those alternations of hope and fear, the continual agitation and exercise which these emotions produce in the mind, that instigate the hunter: they animate him as they do the gamester, the warrior, the sailor, and even to a certain degree, the naturalist of the Alps; whose life, in some measure, pretty much resembles that of the hunter whose manners we have described."

But there is another kind of hunting, which is neither dangerous nor laborious, nor fatal to any one but to the poor animals that are the objects of it.—These are the marmots, animals that inhabit the high mountains; where in summer they scoop out holes, which they line with hay, and retire to at the beginning of autumn: here they grow torpid with the cold, and remain in a sort of lethargy, till the warmth of the spring returns to quicken their languid blood, and to recal them to life. When it is supposed that they have retired to their winter abode, and before the snow has covered the high pastures where their holes are made, people go to unharbour them. They are found from 10 to 12 in the same hole, heaped upon one another, and buried in the hay. Their sleep is so profound, that the hunter often puts them into his bag, and carries them home without their awaking. The flesh of the young is good, though it tastes of oil, and smells somewhat of musk; the fat is used in the cure of rheumatisms and pains, being rubbed on the parts affected; but the skin is of little value, and is sold for no more than five or six sols. Notwithstanding the little benefit they reap from it, the people of Chamouni go in quest of this animal with great eagerness, and its numbers accordingly diminish very sensibly.

It has been said, that marmots, in order to transport the hay into their holes, use one of their number laid on his back as a cart; but this is fabulous, for they are seen carrying the hay in their mouths. Nor is it for food that they gather it, but for a bed, and in order to shut out the cold, and to guard the avenues of their re-

treat from enemies. When they are taken in autumn, Chamouni, their bowels are quite empty, and even as clean as if they had been washed with water; which proves that their torpidity is preceded by a fast, and even by an evacuation: a wise contrivance of Nature for preventing their accumulated feces from growing putrid, or too dry, in the long lethargy they are exposed to. They also continue a few days after their revival without eating, probably to allow the circulation and digestive power to recover their activity. At first, leaving their holes, they appear stupid and dazzled with the light: they are at this time killed with sticks, as they do not endeavour to fly, and their bowels are then also quite empty. They are not very lean when they awake, but grow more so for a few days after they first come abroad. Their blood is never congealed, however profound their sleep may be; for at the time that it is deepest, if they are bled, the blood flows as if they were awake.

In these countries the period is so short between the dissolution of the snow and its return, that grain has hardly time to come to maturity. Mr Saffure mentions a very useful and ingenious practice, invented by mountaineers of the Argentiére, for enlarging this period. "I observed (says he), in the middle of the valley, several large spaces where the surface of the snow exhibited a singular appearance, somewhat resembling a piece of white cloth spotted with black. While I was endeavouring to divine the cause of this phenomenon, I discovered several women walking with measured pace, and sowing something in handfuls that was black; and which being scattered, regularly diverging, on the surface of the snow, formed that spotted appearance that I had been admiring. I could not conceive what seed should be sown on snow six feet deep; but my guide, astonished at my ignorance, informed me, that it was black earth spread upon the snow to accelerate its melting; and thus to anticipate, by a fortnight or three weeks, the time of labouring the fields and sowing. I was struck with the elegant simplicity of a practice so useful, the effects of which I already saw very evidently in places which had not been thus treated above three days.

"As to the inhabitants of Chamouni, the men, like those of most high valleys, are neither well-made nor tall: but they are nervous and strong, as are also the women. They do not attain to a great age; men of 80 are very rare. Inflammatory diseases are the most fatal to them; proceeding, no doubt, from obstructed perspiration, to which the inconstant temperature of the climate exposes them.

"They are in general honest, faithful, and diligent in the practice of religious duties. It would, for instance, be in vain to persuade them to go any where on a holiday before hearing mass. They are economical, but charitable. There are among them neither hospitals nor foundations for the poor; but orphans and old people, who have no means of subsistence, are entertained by every inhabitant of a parish in his turn. If a man is prevented by age or infirmities from taking charge of his affairs, his neighbours join among themselves and do it for him.

"Their mind is active and lively, their temper gay, with an inclination to raillery: they observe, with singular acuteness, the ridiculous in strangers, and turn it

Cham-
pagne
||
Champion.

it into a fund of very facetious merriment among themselves; yet they are capable of serious thinking: many of them have attacked me on religious and metaphysical subjects; not as professing a different faith from theirs; but on general questions, which showed they had ideas independent of those they were taught."

CHAMPAGNE, a considerable province of France, about 162 miles in length, and 112 in breadth, bounded on the north by Hainault and Luxemburg, on the east by Lorraine and the Franche-Comté, on the south by Burgundy, and on the west by the isle of France and Soissonnois. It has a great number of rivers, the principal of which are the Meuse, the Seine, the Marne, the Aube, and the Aine. Its principal trade consists in excellent wine, all sorts of corn, linen cloth, woollen stuffs, cattle, and sheep. It is also divided into the higher and lower, and Troyes is the capital town. Its sub-divisions are Champagne Proper, and Rhemois, the Retelois, the Pertois, the Vallage, Basigni, the Senonois, and the Brie Champenois.

CHAMPAGNE Proper, is one of the eight parts of Champagne, which comprehend the towns of Troyes, Chalons, St Meneshold, Eperney, and Vertus.

CHAMPAIN, or *Point CHAMPAIN*, in heraldry, a mark of dishonour in the coat of arms of him who kills a prisoner of war after he has cried quarter.

CHAMPERTRY, in law, a species of MAINTENANCE, and punished in the same manner; being a bargain with the plaintiff or defendant. *campum partire*, "to divide the land," or other matter sued for between them, if they prevail at law; whereupon the champertor is to carry on the party's suit at his own expence. Thus *Champart*, in the French law, signifies a similar division of profits, being a part of the crop annually due to the landlord by bargain or custom. In our sense of the word, it signifies the purchasing of a suit, or right of suing; a practice so much abhorred by our law, that it is one main reason why a *chose* in action, or thing of which one hath the right but not the possession, is not assignable in common law; because no man should purchase any pretence to sue in another's right. These pests of civil society, that are perpetually endeavouring to disturb the repose of their neighbours, and officiously interfering in other mens quarrels, even at the hazard of their own fortunes, were severally animadverted on by the Roman law; and were punished by the forfeiture of a third part of their goods and perpetual infamy. Hitherto also must be referred the provision of the statute 32 Henry VIII. c. 9. that no one shall sell or purchase any pretended right or title to land, unless the vender hath received the profits thereof for one whole year before such grant, or hath been in actual possession of the land, or of the reversion or remainder; on pain that both purchaser and vender shall each forfeit the value of such land to the king and the prosecutor.

CHAMPION, a person who undertakes a combat in the place or quarrel of another; and sometimes the word is used for him who fights in his own cause.

It appears that champions, in the just sense of the word, were persons who fought instead of those that, by custom, were obliged to accept the duel, but had a just excuse for dispensing with it, as being too old, infirm, or being ecclesiastics, and the like. Such causes as could not be decided by the course of com-

mon law, were often tried by single combat; and he who had the good fortune to conquer, was always reputed to have justice on his side. See the article *BATTEL*.

Champion
||
Chance.

CHAMPION of the King, (*campio regis*), is an ancient officer, whose office is, at the coronation of our kings, when the king is at dinner, to ride armed *cap-a-pee*, into Westminster-Hall, and by the proclamation of an herald make a challenge, "That if any man shall deny the king's title to the crown, he is there ready to defend it in single combat, &c." which being done, the king drinks to him, and sends him a gilt cup with a cover full of wine, which the champion drinks, and hath the cup for his fee. This office, at the coronation of king Richard II. when Baldwin Freville exhibited his petition for it, was adjudged from him to his competitor Sir John Dymocke (both claiming from Marmion), and hath continued ever since in the family of the Dymockes; who hold the manor of Sinvelsby in Lincolnshire, hereditary from the Marmions by grand serjeantry, viz. that the lord thereof shall be the king's champion as aforesaid. Accordingly Sir Edward Dymocke performed this office at the coronation of king Charles II. a person of the name of Dymocke performed at the coronation of his present majesty George the third.

CHAMPLAIN (Samuel de), a celebrated French navigator, the founder of the colony of New France, or Canada. He built Quebec; and was the first governor of the colony in 1603. Died after 1649. See QUEBEC.

CHANANAEI (anc. geog.) the name of the ancient inhabitants of Canaan in general, descendants of Canaan; but peculiarly appropriated to some one branch; though uncertain which branch or son of Canaan it was, or how it happened that they preferred the common gentilitious name to one more appropriated as descendants of one of the sons of Canaan; unless from their course of life, as being in the mercantile way, the import of the name *Canaan*; and for which their situation was greatly adapted, they living on the sea and about Jordan, and thus occupying the greater part of the Land of Promise.

CHANCE, a term we apply to events, to denote that they happen without any necessary or foreknown cause. See CAUSE.

Our aim is, to ascribe those things to *chance*, which are not necessarily produced as the natural effects of any proper cause: but our ignorance and precipitancy lead us to attribute effects to *chance*, which have a necessary and determinate cause.

When we say a thing happens *by chance*, we really mean no more than that its cause is unknown to us: not, as some vainly imagine, that *chance* itself can be the cause of any thing.

The case of the painter, who, unable to express the foam at the mouth of a horse he had painted, threw his sponge in despair at the piece, and, *by chance*, did that which he could not before do by design, is an eminent instance of the force of *chance*: yet, it is obvious, all we here mean by *chance*, is, that the painter was not aware of the effect; or that he did not throw the sponge with such a view: not but that he actually did every thing necessary to produce the effect; inasmuch, that, considering the direction wherein

Chance. wherein he threw his sponge, together with its form, specific gravity, the colours wherewith it was smeared, and the distance of the hand from the piece, it was impossible, on the present system of things, the effect should not follow.

Chance is frequently personified, and erected into a chimerical being, whom we conceive as acting arbitrarily, and producing all the effects whose real causes do not appear to us: in which sense the word coincides with the *τυχη*, *fortuna*, of the ancients.

CHANCE is also used for the manner of deciding things, the conduct or direction whereof is left at large, and not reducible to any determinate rules or measures; or where there is no ground for preference: as at cards, dice, lotteries, &c.

For the *Laws of CHANCE, or the Proportion of Hazard in Gaming*, see **GAME**.

The ancient *sortilege*, or *chance*, M. Placette observes, was instituted by God himself; and in the Old Testament we find several standing laws and express commands which prescribed its use on certain occasions: hence the Scripture says, "The lot, or *chance*, fell on Matthias," when it was in question who should fill Judas's place in the apostolate.

Hence also arose the *sortes sanctorum*; or method of determining things, among the ancient Christians, by opening some of the sacred books, and pitching on the first verse they cast their eye on, as a sure prognostic of what was to befall them. The *sortes Homericae, Virgilianae, Prænestinae*, &c. used by the heathens, were with the same view, and in the same manner. See **SORTES**.

St Augustin seems to approve of this method of determining things future, and owns that he had practised it himself; grounded on this supposition, that God presides over *chance*; and on Prov. xvi. 33.

Many among the modern divines hold *chance* to be conducted in a particular manner by Providence; and esteem it an extraordinary way which God uses to declare his will, and a kind of immediate revelation.

CHANCE-Medley, in law, is where one is doing a lawful act, and a person is killed by chance thereby; for if the act be unlawful, it is felony. If a person cast, not intending harm, a stone, which happens to hit one, whereof he dies; or shoots an arrow in an highway, and another that passeth by is killed therewith; or if a workman, in throwing down rubbish from a house after warning to take care, kills a person; or a schoolmaster in correcting his scholar, a master his servant, or an officer in whipping a criminal in a reasonable manner, happens to occasion his death; it is chance-medley and misadventure. But if a man throw stones in a highway where persons usually pass; or shoot an arrow, &c. in a market-place among a great many people; or if a workman cast down rubbish from a house in cities and towns where people are continually passing; or a schoolmaster, &c. correct his servant or scholar, &c. exceeding the bounds of moderation; it is manslaughter: and if with an improper instrument of correction, as with a sword or iron bar, or by kicking, stamping, &c. in a cruel manner, it is murder. If a man whips his horse in a street to make him gallop, and the horse runs over a child and kills it, it is manslaughter: but if another whips

Nº 69.

the horse, it is manslaughter in him, and chance-medley in the rider. And if two are fighting; and a third person coming to part them is killed by one of them without any evil intent, yet this is murder in him, and not manslaughter by chance medley or misadventure. In chance-medley, the offender forfeits his goods; but hath a pardon of course.

CHANCEL, is properly that part of the choir of a church, between the altar or communion-table and the balustrade or rail that incloses it, where the minister is placed at the celebration of the communion. The word comes from the Latin *cancellus*, which in the lower Latin is used in the same sense, from *cancelli*, "lattices or cross bars," wherewith the chancels were anciently encompassed, as they now are with rails. The right of a seat and a sepulchre in the chancels is one of the privileges of founders.

CHANCELLOR, was at first only a chief notary or scribe under the emperors; and was called *cancellarius*, because he sat behind a lattice (in Latin *cancellus*) to avoid being crowded by the people: though some derive the word from *cancellare*, "to cancel" (See **CHANCERY**). This officer was afterwards invested with several judicial powers, and a general superintendency over the rest of the officers of the prince. From the Roman empire it passed to the Roman church, ever emulous of imperial state: and hence every bishop has to this day his chancellor, the principal judge of his consistory. And when the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor with different jurisdictions and dignities, according to their different constitutions. But in all of them he seems to have had the supervision of all charters, letters, and such other public instruments of the crown as were authenticated in the most solemn manner: and therefore, when seals came in use, he had always the custody of the king's great seal.

Lord High CHANCELLOR of Great Britain, or **Lord Keeper of the Great Seal**, is the highest honour of the long robe, being created by the mere delivery of the king's great seal into his custody; whereby he becomes, without writ or patent, an officer of the greatest weight and power of any now subsisting in the kingdom. He is a privy counsellor by his office; and, according to Lord Chancellor Ellesmere, prolocutor of the house of lords by prescription. To him belongs the appointment of all the justices of the peace throughout the kingdom. Being in former times commonly an ecclesiastic (for none else were then capable of an office so conversant in writing), and presiding over the royal chapel, he became keeper of the king's conscience; visitor, in right of the king, of all hospitals and colleges of the king's foundation; and patron of all the king's livings under the value of L. 20 *per annum* in the king's books. He is the general guardian of all infants, idiots, and lunatics; and has the general superintendence of all charitable uses in the kingdom. And all this over and above the vast extensive jurisdiction which he exercises in his judicial capacity in the court of chancery. He takes precedence of every temporal lord except the royal family, and of all others except the archbishop of Canterbury. See **CHANCERY**.

CHANCELLOR, in Scotland, was the chief in matters of justice. In the laws of King Malcolm II. he is placed

Chancellor. placed before all other officers; and from these it appears, that he had the principal direction of the Chancery, or Chancellery as it is called, which is his proper office. He had the custody of the king's seal; and he was the king's most intimate counsellor, as appears by an old law cited by Sir James Balfour: "The chancellor shall at all times assist the king, in giving him counsellor mair secretly nor the rest of the nobility, to quais ordinances all officiaris, als well of the realme as of the kingis hous, sould answer and obey. The chancellor shall be ludgit neir unto the kingis grace, for keeping of his bodie, and the seill; and that he may be readie baith day and nicht at the kingis command." By having the custody of the great seal, he had an opportunity of examining the king's grants and other deeds which were to pass under it, and to cancel them if they appeared against law, and were obtained surreptitiously or by false suggestions.

King James VI. ordained the chancellor to have the first place and rank in the nation, *ratione officii*; by virtue whereof he presided in the parliament, and in all courts of judicature. After the restoration of King Charles II. by a particular declaratory law, parliament first, the lord chancellor was declared, by virtue and right of his office, president in all the meetings of parliament, or other public judicatures of the kingdom. Although this act was made to declare the chancellor president of the exchequer as well as other courts, yet in 1663 the king declared the treasurer to be president of that court.

The office of lord chancellor was abolished by the Union, there being no farther use for the judicial part of this office; and, to answer all the other parts of the chancellor's office, a lord keeper of the great seal was erected, with a salary of L. 3000 a-year.

CHANCELLOR of a Cathedral, an officer that hears lessons and lectures read in the church, either by himself or his vicar; to correct and set right the reader when he reads amiss; to inspect schools; to hear causes; apply the seal; write and dispatch the letters of the chapter; keep the books; take care that there be frequent preachings, both in the church and out of it; and assign the office of preaching to whom he pleases.

CHANCELLOR of the Duchy of Lancaster, an officer appointed chiefly to determine controversies between the king and his tenants of the duchy-land, and otherwise to direct all the king's affairs belonging to that court. See *DUCHY-Court*.

CHANCELLOR of the Exchequer, an officer who presides in that court, and takes care of the interest of the crown. He is always in commission with the lord-treasurer, for the letting of crown-lands, &c. and has power, with others, to compound for forfeitures of lands upon penal statutes. He has also great authority in managing the royal revenues, and in matters relating to the first-fruits.

CHANCELLOR of the Order of the Garter, and other Military Orders, is an officer who seals the commissions and mandates of the chapter and assembly of the knights, keeps the register of their proceedings, and delivers acts thereof under the seal of their order.

CHANCELLOR of an University, is he who seals the diplomas, or letters of degrees, provision, &c. given in the university.

VOL. IV. Part I.

The chancellor of Oxford is usually one of the prime nobility, chosen by the students themselves in convocation. He is their chief magistrate; his office is, *durante vita*, to govern the university, preserve and defend its rights and privileges, convoke assemblies, and do justice among the members under his jurisdiction.

Under the chancellor is the vice-chancellor, who is chosen annually, being nominated by the chancellor, and elected by the university in convocation. He is always the head of some college, and in holy orders. His proper office is to execute the chancellor's power, to govern the university according to her statutes, to see that officers and students do their duty, that courts be duly called, &c. When he enters upon his office, he chooses four pro-vice-chancellors out of the heads of the colleges, to execute his power in his absence.

The chancellor of Cambridge is also usually one of the prime nobility, and in most respects the same as that in Oxford; only he does not hold his office *durante vita*, but may be elected every three years. Under the chancellor there is a commissary, who holds a court of record for all privileged persons and scholars under the degree of master of arts, where all causes are tried and determined by the civil and statute law, and by the custom of the university.

The vice-chancellor of Cambridge is chosen annually by the senate, out of two persons nominated by the heads of the several colleges and halls.

CHANCELLOR'S COURT. See *UNIVERSITY-Courts*.

CHANCERON, in natural history, a name given by the French writers to the small caterpillar that eats the corn, and does vast mischief in their granaries. See the article *CORN-Butterfly*.

CHANCERY, the highest court of justice in Britain next to the parliament, and of very ancient institution. It has its name chancery (*cancellaria*) from the judge who presides here, the lord chancellor, or *cancellarius*; who, according to Sir Edward Coke, is so termed a *cancellando*, from cancelling the king's letters patent when granted contrary to law, which is the highest point of his jurisdiction. In chancery there are two distinct tribunals: the one ordinary, being a court of common law; the other extraordinary, being a court of equity.

1. The ordinary legal court holds pleas of recognizances acknowledged in the chancery, writs of *scire facias*, for repeal of letters patent, writs of partition, &c. and also of all personal actions by or against any officer of the court. Sometimes a *superfedeas*, or writ of privilege, hath been here granted to discharge a person out of prison; one from hence may have a *habeas corpus* prohibition, &c. in the vacation; and here a *subpoena* may be had to force witnesses to appear in other courts, when they have no power to call them. But, in prosecuting causes, if the parties descend to issue, this court cannot try it by jury; but the lord chancellor delivers the record into the king's bench to be tried there; and after trial had, it is to be remanded into the chancery, and there judgment given: tho' if there be a demurrer in law, it shall be argued in this court.

In this court is also kept the *officina justitie*; out of which all original writs that pass under the great seal, all commissions of charitable uses, sewers, bankruptcy,

Blackst.
Comment.

Chancery. idiocy, lunacy, and the like, do issue; and for which it is always open to the subject, who may there at any time demand and have, *ex debito justitiæ*, any writ that his occasions may call for. These writs, relating to the business of the subject, and the returns of them, were, according to the simplicity of ancient times, originally kept in a hamper, *in hanaperio*; and the others (relating to such matters wherein the crown is mediately or immediately concerned) were preserved in a little sack or bag, *in parva бага*; and hence hath arisen the distinction of the *hanaper* office, and the *petty-bag* office, which both belong to the common law-court in chancery.

2. The *extraordinary* court, or court of equity, proceeds by the rules of equity and conscience; and moderates the rigour of the common law, considering the *intention* rather than the *words* of the law. It gives relief for and against infants notwithstanding their minority, and for and against married women notwithstanding their coverture. All frauds and deceits for which there is no redress at common law; all breaches of trust and confidence; and accidents, as to relieve obligors, mortgagers, &c. against penalties and forfeitures, where the intent was to pay the debt, are here remedied: for in chancery, a forfeiture, &c. shall not bind, where a thing may be done after or compensation made for it. Also this court will give relief against the extremity of unreasonable engagements entered into without consideration; oblige creditors that are unreasonable to compound with an unfortunate debtor; and make executors, &c. give security and pay interest for money that is to lie long in their hands. This court may confirm title to lands, though one hath lost his writings; and render conveyances, defective through mistake, &c. good and perfect. In chancery, copy-holders may be relieved against the ill usage of their lords; inclosures of lands that are common be decreed; and this court may decree money or lands given to charitable uses, oblige men to account with each other, &c. But in all cases where the plaintiff can have his remedy at law, he ought not to be relieved in chancery; and a thing which may be tried by a jury is not triable in this court.

The proceedings in chancery are, first to file the bill of complaint, signed by some counsel, setting forth the fraud or injury done, or wrong sustained, and praying relief: after the bill is filed, process of *subpena* issues to compel the defendant to appear; and when the defendant appears, he puts in his answer to the bill of complaint, if there be no cause for the plea to the jurisdiction of the court, in disability of the person, or in bar, &c. Then the plaintiff brings his replication, unless he files exceptions against the answer as insufficient, referring it to a master to report whether it be sufficient or not; to which report exceptions may also be made. The answer, replication, rejoinder, &c. being settled, and the parties come to issue, witnesses are to be examined upon interrogatories, either in court or by commission in the country, wherein the parties usually join; and when the plaintiff and defendant have examined their witnesses, publication is to be made of the depositions, and the cause is to be set down for hearing; after which follows the decree. But it is now usual to appeal to the house of lords; which appeals are to be signed by two noted counsel, and exhibited by way

of petition; the petition or appeal is lodged with the **Chandelier** clerk of the house of lords, and read in the house, whereon the appellee is ordered to put in his answer, and a day fixed for hearing the cause; and after counsel heard, and evidence given on both sides, the lords will affirm or reverse the decree of the chancery, and finally determine the cause by a majority of votes, &c.

CHANDELIER, in fortification, a kind of moveable parapet, consisting of a wooden frame, made of two upright stakes, about six feet high, with cross planks between them; serving to support fascines to cover the pioneers.

CHANDERNAGORE, a French settlement in the kingdom of Bengal in the East Indies. It lies on the river Ganges, two leagues and a half above Calcutta. The district is hardly a league in circumference, and has the disadvantage of being somewhat exposed on the western side; but its harbour is excellent, and the air is as pure as it can be on the banks of the Ganges. Whenever any building is undertaken that requires strength, it must here, as well as in all other parts of Bengal, be built upon piles; it being impossible to dig three or four feet without coming at water.

CHANDLER (Mary), distinguished by her talent for poetry, was the daughter of a dissenting minister at Bath; and was born at Malmesbury in Wiltshire in 1687. She was bred a milliner; but from her childhood had a turn for poetry, and in her riper years applied herself to the study of the poets. Her poems, for which she was complimented by Mr Pope, breathe the spirit of piety and philosophy. She had the misfortune to be deformed, which determined her to live single; though she had great sweetness of countenance, and was solicited to marry. She died in 1745, aged 58.

CHANDLER (Dr Samuel), a learned and respectable dissenting minister, descended from ancestors heartily engaged in the cause of religious liberty, and sufferers for the sake of conscience and nonconformity; was born at Hungerford in Berks, where his father was a minister of considerable worth and abilities. Being by his literary turn destined to the ministry, he was first placed at an academy at Bridgewater, and from thence removed to Gloucester under Mr Samuel Jones. Among the pupils of Mr Jones were Mr Joseph Butler, afterwards bishop of Durham, and Mr Thomas Secker, afterwards archbishop of Canterbury. With these eminent persons he contracted a friendship that continued to the end of their lives, notwithstanding the different views by which their conduct was afterwards directed, and the different situations in which they were placed.

Mr Chandler having finished his academical studies, began to preach about July 1714; and being soon distinguished by his talents in the pulpit, he was chosen in 1716 minister of the Presbyterian congregation at Peckham near London, in which station he continued some years. Here he entered in the matrimonial state, and began to have an increasing family, when, by the fatal South-sea scheme of 1720, he unfortunately lost the whole fortune which he had received with his wife. His circumstances being thereby embarrassed, and his income as a minister being inadequate to his expences, he engaged in the trade of a bookseller, and kept a shop in the Poultry, London, for about two or three years.

Chandler

years, still continuing to discharge the duties of the pastoral office. He also officiated as joint preacher with the learned Dr Lardner of a winter weekly evening lecture at the meeting-house in the Old Jewry, London: in which meeting he was established assistant preacher about the year 1725; and then as the pastor. Here he ministered to the religious improvement of a very respectable congregation for 40 years with the greatest applause; and with what diligence and application he improved the vacancies of time from his pastoral duties, for improving himself and benefiting the world, will appear from his many writings on a variety of important subjects. While he was thus laudably employed, not only the universities of Edinburgh and Aberdeen gave him, without any application, testimonies of their esteem in diplomas, conferring on him the degree of D. D. but he also received offers of preferment from some of the governors of the established church, which he nobly declined. He had likewise the honour of being afterwards elected F. R. and A. SS.

On the death of George II. in 1760, Dr Chandler published a sermon on that event, in which he compared that prince to King David. This gave rise to a pamphlet, which was printed in the year 1761, intitled "The History of the Man after God's own Heart;" wherein the author ventured to exhibit King David as an example of perfidy, lust, and cruelty, fit only to be ranked with a Nero or a Caligula; and complained of the insult that had been offered to the memory of the late British monarch by Dr Chandler's parallel between him and the king of Israel. This attack occasioned Dr Chandler to publish in the following year "A Review of the History of the Man after God's own Heart; in which the Falsehoods and Misrepresentations of the Historian are exposed and corrected." He also prepared for the press a more elaborate work, which was afterwards published in two volumes 8vo, under the following title: "A Critical History of the Life of David: in which the principal Events are ranged in Order of time; the chief Objections of Mr Bayle and others against the Character of this Prince, and the Scripture Account of him, and the Occurrences of his Reign, are examined and refuted; and the Psalms which refer to him explained." As this was the last, it was likewise one of the best, of Dr Chandler's productions. The greatest part of this work was printed off at the time of our author's death, which happened May 8th 1766, aged 73. During the last year of his life, he was visited with frequent returns of a very painful disorder, which he endured with great resignation and Christian fortitude. He was interred in the burying-ground at Bunhill-fields on the 16th of the month; and his funeral was very honourably attended by ministers and other gentlemen. He expressly desired, by his last will, that no delineation of his character might be given in his funeral sermon, which was preached by Dr Amory. He had several children; two sons and a daughter who died before him, and three daughters who survived him; two of whom are yet living, and both married, one of them to the Rev. Dr Harwood.

Dr Chandler was a man of very extensive learning and eminent abilities; his apprehension was quick and his judgment penetrating; he had a warm and vigorous imagination; he was a very instructive and animated preach-

er; and his talents in the pulpit and as a writer procured him very great and general esteem, not only among the dissenters, but among large numbers of the established church. He was principally instrumental in the establishment of the fund for relieving the widows and orphans of poor Protestant dissenting ministers: the plan of it was first formed by him; and it was by his interest and application to his friends that many of the subscriptions for its support were procured.

In 1768, four volumes of our author's sermons were published by Dr Amory, according to his own directions in his last will; to which was prefixed a neat engraving of him, from an excellent portrait by Mr Chamberlin. He also expressed a desire to have some of his principal pieces reprinted in four volumes 8vo: proposals were accordingly published for that purpose, but did not meet with sufficient encouragement. But in 1777, another work of our author was published in one volume 4to, under the following title: "A Paraphrase and Notes on the Epistles of St Paul to the Galatians and Ephesians, with doctrinal and practical Observations: together with a critical and practical Commentary on the two Epistles of St Paul to the Thessalonians." Dr Chandler also left, in his interleaved Bible, a large number of critical notes, chiefly in Latin, which are now the property of Dr Kippis, Mr Farmer, Dr Price, and Dr Savage, and which have been intended to be published; but the design has not yet been executed. A complete list of Dr Chandler's works is given in the *Biographia Britannica*, vol. III. p. 435.

CHANG-TONG, a province of China, bounded on the east by Petcheli and part of Honan, on the south by Kiang-nan, on the east by the sea, and on the north by the sea and part of Petcheli. The country is well watered by lakes, streams, and rivers; but is nevertheless liable to suffer from drought, as rain falls here but seldom. The locusts also sometimes make great devastation. However, it abounds greatly in game; and there is perhaps no country where quails, partridges, and pheasants, are sold cheaper, the inhabitants of this province being reckoned the keenest sportsmen in the empire. The province is greatly enriched by the river Yun, called the *Grand Imperial Canal*, through which all the barks bound to Peking must pass in their way thither. The duties on this canal alone amount to more than L.450,000 annually. The canal itself is greatly admired by European travellers on account of its strong and long dikes, the banks decorated with cut stone, the ingenious mechanism of its locks, and the great number of natural obstacles which have been overcome in the execution of the work.—The province produces silk of the ordinary kind; and, besides this, another from a sort of insect resembling our caterpillar. It is coarser than the ordinary silk, but much stronger and more durable; so that the stuffs made from it have a very extensive sale throughout the empire.

Chang-tong is remarkable for being the birth-place of the celebrated philosopher and lawgiver Confucius. His native city is called *Kio-seou*, where there are several monuments erected in honour of this great man. The province is divided into six districts, which contain six cities of the first class, and 114 of the second

Chandler,
Chang-
tong.

Chang-
tong
||
Changes.

and third. Along the coast, also, are 15 or 16 villages of considerable importance on account of their commerce; there are likewise a number of small islands, most of which have harbours very convenient for the Chinese junks which pass from thence to Corea or Lea-tong. The most remarkable cities are, 1. Tsi-nan-fou, the capital, which stands south of the river Tchingho or Tsi. It is large and populous; but chiefly celebrated for having been the residence of a long series of kings, whose tombs, rising on the neighbouring mountains, afford a beautiful prospect. 2. Yen-tcheu-fou, the second city of the province, situated between two rivers, and in a mild and temperate climate. Great quantities of gold are said to have been formerly collected in its neighbourhood. 3. Lin-tsin-tcheu, situated on the great canal, is much frequented by ships, and may be called a general magazine for every kind of merchandise. Here is an octagonal tower, divided into eight stories, the walls of which are covered on the outside with porcelain loaded with various figures neatly executed, and encrusted on the inside with variously coloured marble. A staircase, constructed in the wall, conducts to all the stories, from which there are passages that lead into magnificent galleries ornamented with gilt ballustrades. All the cornices and projections of the tower are furnished with little bells; which, says Mr Grosier, when agitated by the wind, form a very agreeable harmony. In the highest story is an idol of gilt copper, to which the tower is dedicated. In the neighbourhood are some other temples, the architecture of which is exceedingly beautiful.

CHANGER, an officer belonging to the king's mint, who changes money for gold or silver bullion. See MINT.

Money-CHANGER, is a banker who deals in the exchange, receipt, and payment, of moneys. See BANKER.

CHANGES, in arithmetic, &c. the permutations or variations of any number of quantities; with regard to their position, order, &c. See COMBINATION.

To find all the possible CHANGES of any Number of Quantities, or how oft their Order may be varied. Suppose two quantities a and b . Since they may be either wrote ab or ba , it is evident their changes are $2 = 2.1$. Suppose three quantities $a b c$: their changes will be as in the margin; as is evident by combining c first with ab , then with ba ; and hence the number of changes arises $3.2.1 = 6$. If the quantities be 4, each may be combined four ways with each order of the other three; whence the number of changes arises $6.4 = 24$. Wherefore, if the number of quantities be supposed n , the number of changes will be $n.n-1.n-2.n-3.n-4$. &c. If the same quantity occur twice, the changes of two will be found bb ; of three, bab, abb, bcb ; of four, cba, bca, bcb . And thus the number of changes in the first case will be $1 = (2.1): 2.1$; in the second, $3 = (3.2.1): 2.1$; in the third, $12 = (4.3.2.1): 2.1$.

If a fifth letter be added, in each series of four quantities, it will beget five changes, whence the number of all the changes will be $60 = (5.4.3.2.1): 2.1$. Hence if the number of quantities be n , the number of changes will be $(n.n-1.n-2.n-3.n-4. \&c.): 2.1$.

From these special formulæ may be collected a general one, viz. if n be the number of quantities, and m the number which shows how oft the same quantity occurs; we shall have $(n.n-1.n-2.n-3.n-4.n-5.n-6.n-7.n-8.n-9. \&c.): m-1.m-2.m-3.m-4. \&c.)$ the series being to be continued, till the continual subtraction of unity from n and m leave 0. After the same manner we may proceed further, till putting n for the number of quantities, and $l, m, r, \&c.$ for the number that shows how oft any of them is repeated, we arrive at an universal form. $(n.n-1.n-2.n-3.n-4.n-5.n-6.n-7.n-8. \&c.): (l.l-1.l-2.l-3.l-4.l-5. \&c. m.m-1.m-2.m-3. \&c. r.r-1.r-2.r-3.r-4.r-5. \&c.)$

Suppose, for instance, $n=6, l=3, r=0$. The number of changes will be $(6.5.4.3.2.1): (3.2.1.3.2.1) = (6.5.4): (3.2 = 2.5.2 = 20)$.

Hence, suppose thirteen persons at a table, if it be required how oft they may change places; we shall find the number $13.12.11.10.9.8.7.6.5.4.3.2.1 = 6227020800$.

In this manner may all the possible anagrams of any word be found in all languages, and that without any study: suppose *v. g.* it were required to find the anagrams of the word *amor*, the number of changes will be

<i>a</i>	<i>o a m</i>	<i>r m o a</i>	<i>m a r o</i>	<i>a r o m</i>
—	<i>a o m</i>	<i>m r o a</i>	<i>m a o r</i>	<i>a o r m</i>
<i>m a</i>	<i>a m o</i>	<i>m o r a</i>	—	<i>a o m r</i>
<i>a m</i>	—	<i>m o a r</i>	<i>r a o m</i>	—
—	<i>r o m a</i>	—	<i>o r a m</i>	<i>r a m o</i>
<i>o m a</i>	<i>o r m a</i>	<i>r m a o</i>	<i>o a r m</i>	<i>a r m o</i>
<i>m o a</i>	<i>o m r a</i>	<i>m r a o</i>	<i>o a m r</i>	<i>a m r o</i>
<i>m a o</i>	<i>o m a r</i>	—	—	<i>a m o r</i>
			<i>r a o m</i>	

The anagrams therefore of the word *amor*, in the Latin tongue, are *roma, mara, maro, ramo, armo*. See ANAGRAM.

Whether this new method of anagramatizing be like to prove of much service to that art, is left to the poets.

CHANNA, in zoology, the name of a fish caught in great plenty in the Mediterranean, and brought to market in Italy and elsewhere, among the sea-perch, which it so nearly resembles, that it would not be distinguishable from it, but that the sea-perch is bigger, and has only broad transverse lines on its back, whereas the channa has them both transverse and longitudinal. It has a very wide mouth, and its lower jaw is longer than its upper; so that its mouth naturally falls open. Its eyes are small, and its teeth very sharp: its back is of a blackish red: it has several longitudinal lines of a reddish hue, and its tail is marked with reddish spots. There is an observation, that in all the fish of this kind which have been examined by naturalists, there have been found none but females. This is as old as the days of Aristotle. Whether this be true in fact, would require many observations. If it should prove so, the whole seems to end in this, that the channa is no distinct species, but only the female of some other fish. There is another fish not unlike this, called *cannadella*, or rather *channadella*, which at Marseilles is known by the name of *charina*.

CHANNEL, in geography, an arm of the sea, or a narrow sea between two continents, or between a continent

Changes
||
Channel.

Channel

Chant.

continent and an island. Such are the British channel, St George's channel, the channel of Constantinople, &c.

CHANNEL of a Ship. See *CHAIN-Wales*.

CHAN-SI, a province of China, and one of the smallest in the empire, is bounded on the east by Petcheli, on the south by Honan, on the west by Chen-fi, and on the north by the great wall. The climate is healthful and agreeable, and the soil generally fertile, though the country is full of mountains. Some of these last are rough, wild, and uninhabited; but others are cultivated with the greatest care from top to bottom, and cut into terraces, forming a very agreeable prospect; while some have on their tops vast plains no less fertile than the richest low-lands. These mountains abound with coal, which the inhabitants pound and make into cakes with water; a kind of fuel which, though not very inflammable, affords a strong and lasting fuel when once kindled. It is principally used for heating their stoves, which are constructed with brick as in Germany; but the inhabitants of this province give them the form of small beds, and sleep upon them. The best grapes to be met with in this part of Asia grow in the province of Chan-fi; so that good wine might be made, but the people choose rather to dry and sell them to the neighbouring provinces. The country abounds with musk, porphyry, marble, lapis lazuli, and jasper of various colours; and iron mines as well as salt-pits and crystal are very common. Here are five cities of the first class, and eighty-five of the second and third: the most remarkable are, 1. Tai-youen-fou the capital, an ancient city about three leagues circumference, but much decayed in consequence of being no longer the residence of the princes of the blood as it was formerly. Nothing now remains of the palaces of those princes but a few ruins; but their tombs are still to be seen on a neighbouring mountain. The burying-place is magnificently ornamented; and all the tombs are of marble or cut stone, having near them triumphal arches, statues of heroes, figures of lions and different animals, especially horses, and which are disposed in very elegant order. An awful and melancholy gloom is preserved around these tombs by groves of aged cypresses, which have never felt the stroke of an axe, placed chequer-wise. The principal articles of trade here are, hard-ware, stuffs of different kinds, particularly carpets in imitation of those of Turkey. 2. Ngan-y is situated near a lake as salt as the ocean, from which a great quantity of salt is extracted. 3. Fuen-tcheou-fou, an ancient and commercial city, built on the banks of the river Fuenho: it has baths and springs almost boiling hot, which by drawing hither a great number of strangers, add greatly to its opulence. 4. Tai-tong-fou, situated near the wall, is a place of great strength, and important by reason of its situation, as being the only one exposed to the incursions of the Tartars. Its territories abound with lapis lazuli, medicinal herbs, and a particular kind of jasper called *yieche*, which is as white and beautiful as agate; marble and porphyry are also common; and a great revenue is produced from the skins which are dressed here.

CHANT, (*cantus*), is used for the vocal music of churches.

In church-history we meet with divers kinds of

chant or song. The first is the *Ambrosian*, established by St Ambrose. The second, the *Gregorian chant*, introduced by Pope Gregory the great, who established schools of chantors, and corrected the church-song. This is still retained in the church under the name of *plain song*: at first it was called the *Roman song*. The *plain* or *Gregorian chant*, is where the choir and people sing in unison, or all together in the same manner.

CHANTILLY, a village in France, about seven leagues from Paris, where there is a magnificent palace and fine forest belonging to the duke of Bourbon.

CHANTOR, a singer of a choir in a cathedral. The word is almost grown obsolete, *chorister* or *singing-man* being commonly used instead of it. All great chapters have chantors and chaplains to assist the canons, and officiate in their absence.

CHANTOR is used by way of excellence for the precentor or master of the choir, which is one of the first dignities of the chapter. At St David's in Wales, where there is no dean, he is next in dignity to the bishop. The ancients called the chantor *primicerius cantorum*. To him belonged the direction of the deacons and other inferior officers.

Chantors, in the temple of Jerusalem, were a number of Levites employed in singing the praises of God, and playing upon instruments before his altar. They had no habits distinct from the rest of the people; yet in the ceremony of removing the ark to Solomon's temple, the chantors appeared dressed in tunics of byssus or fine linen. 2 Chron. v. 12.

CHANTRY, or **CHAUNTRY**, was anciently a church or chapel endowed with lands, or other yearly revenue, for the maintenance of one or more priests, daily saying or singing mass for the souls of the donors, and such others as they appointed. Hence *chantry-rents* are rents paid to the crown by the tenants or purchasers of *chantry lands*.

CHAOLGY, the history or description of the chaos. See **CHAOS**.

Orpheus, in his chaology, sets forth the different alterations, secretions, and divers forms which matter went through till it became inhabitable, which amounts to the same with what we otherwise call *cosmogony*. Dr Burnet, in his theory of the earth, represents the chaos as it was at first, entire, undivided, and universally rude and deformed; or the *tohu bobu*: then shows how it came to be divided into its respective regions; how the homogeneous matter gathered itself apart from all of a contrary principle; and lastly, how it hardened, and became a solid habitable globe. See **EARTH**.

CHAOS, that confusion in which matter lay when newly produced out of nothing at the beginning of the world, before God, by his almighty word, had put it into the order and condition wherein it was after the six days creation. See **EARTH**.

Chaos is represented by the ancients as the first principle, ovum, or seed of nature and the world. All the sophists, sages, naturalists, philosophers, theologues, and poets, held that chaos was the eldest and first principle; το αρχαιον χαος. The Barbarians, Phœnicians, Egyptians, Persians, &c. all refer the origin of the world to a rude, mixed, confused mass of matter. The Greeks, Orpheus, Hesiod, Menander, Aristophanes, Euripides, and the writers of the Cyclic Poems, all speak

Chantilly
||
Chaos.

Chaos
||
Chapeau.

Chaos speak of the first chaos: the Ionic and Platonic philosophers build the world out of it. The Stoics hold, that as the world was first made of a chaos, it shall at last be reduced to a chaos; and that its periods and revolutions in the mean time are only transitions from one chaos to another. Lastly, the Latins, as Ennius, Varro, Ovid, Lucretius, Statius, &c. are all of the same opinion. Nor is there any sect or nation whatever, that does not derive their *διακοσμησις*, the structure of the world, from a chaos.

The opinion first arose among the Barbarians, whence it spread to the Greeks, and from the Greeks to the Romans and other nations. Dr Burnet observes, that besides Aristotle and a few other pseudo-Pythagoreans, nobody ever asserted that our world was always from eternity of the same nature, form, and structure, as at present; but that it had been the standing opinion of the wise men of all ages, that what we now call the *terrestrial globe*, was originally an unformed, indigested mass of heterogeneous matter, called *chaos*; and no more than the rudiments and materials of the present world.

It does not appear who first broached the notion of a chaos. Moses, the eldest of all writers, derives the origin of this world from a confusion of matter, dark, void, deep, without form, which he calls *tobu boh*; which is precisely the chaos of the Greek and Barbarian philosophers. Moses goes no further than the chaos; nor tells us whence it took its origin, or whence its confused state; and where Moses stops, there, precisely, do all the rest. Dr Burnet endeavours to show, that as the ancient philosophers, &c. who wrote of the cosmogony, acknowledged a chaos for the principle of their world; so the divines, or writers of the theogony, derive the origin or generation of their fabled gods from the same principle.

Mr Whiston supposes the ancient chaos, the origin of our earth, to have been the atmosphere of a comet; which, though new, yet, all things considered, is not the most improbable assertion. He endeavours to make it out by many arguments, drawn from the agreement which appears to be between them. So that, according to him, every planet is a comet, formed into a regular and lasting constitution, and placed at a proper distance from the sun, revolving in a nearly circular orbit: and a comet is a planet either beginning to be destroyed or re-made; that is, a chaos or planet unformed or in its primæval state, and placed as yet in an orbit very eccentric.

CHAOS, in the phrase of Paracelsus, imports the air. It has also some other significations amongst the alchemists.

CHAOS, in zoology, a genus of insects belonging to the order of vermes zoophyta. The body has no shell or covering, and is capable of reviving after being dead to appearance for a long time: it has no joints or external organs of sensation. There are five species, mostly obtained by infusions of different vegetables in water, and only discoverable by the microscope. See ANIMALCULE.

CHAPEAU, in heraldry, an ancient cap of dignity worn by dukes, being scarlet-coloured velvet on the outside, and lined with a fur. It is frequently borne above an helmet instead of a wreath, under gentlemen's crests.

Chapel
||
Chapelet.

CHAPEL, a place of divine worship, so called. The word is derived from the Latin *capella*. In former times, when the kings of France were engaged in war, they always carried St Martin's hat into the field, which was kept in a tent as a precious relic: from whence the place was called *capella*; and the priests, who had the custody of the tent, *capellani*. Afterwards the word *capella* became applied to private oratories.

In Britain there are several sorts of chapels. 1. Parochial chapels: these differ from parish-churches only in name; they are generally small, and the inhabitants within the district few. If there be a presentation *ad ecclesiam*, instead of *capellam*, and an admission and institution upon it, it is no longer a chapel, but a church. 2. Chapels, which adjoin to, and are part of the church: such were formerly built by honourable persons, as burying-places for themselves and their families. 3. Chapels of ease: these are usually built in very large parishes, where all the people cannot conveniently repair to the mother-church. 4. Free chapels; such as were founded by kings of England. They are free from all episcopal jurisdiction, and only to be visited by the founder and his successors; which is done by the lord chancellor: yet the king may license any subject to build and endow a chapel, and by letters patent exempt it from the visitation of the ordinary. 5. Chapels in the universities, belonging to particular colleges. 6. Domestic chapels, built by noblemen or gentlemen for the private service of God in their families. See CHAPLAIN.

CHAPEL is also a name given to a printer's workhouse; because, according to some authors, printing was first actually performed in chapels or churches; or, according to others, because Caxton, an early printer, exercised the art in one of the chapels in Westminster Abbey. In this sense they say, *the orders or laws of the chapel, the secrets of the chapel*, &c.

Knights of the CHAPEL, called also *Poor knights of Windsor*, were instituted by Henry VIII. in his testament. Their number was at first thirteen, but has been since augmented to twenty-six. They assist in the funeral services of the kings of England: they are subject to the office of the canons of Windsor, and live on pensions assigned them by the order of the garter. They bear a blue or red cloak, with the arms of St George on the left shoulder.

CHAPELAIN (James), an eminent French poet born at Paris in 1595, and often mentioned in the works of Balzac, Menage, and other learned men. He wrote several works, and at length distinguished himself by an heroic poem called *La Pucelle, ou France Delivrée*, which employed him several years; and which, raising the expectation of the public, was as much decried by some as extolled by others. He was one of the king's counsellors; and died in 1674, very rich, but was very covetous and sordid.

CHAPELET, in the manege, a couple of stirrup-leathers, mounted each of them with a stirrup, and joined at top in a sort of leather buckle, called the *head of the chapelet*, by which they are made fast to the pommel of the saddle, after being adjusted to the rider's length and bore. They are used both to avoid the trouble of taking up or letting down the stirrups every time that the gentleman mounts on a different horse and

Chapelle
||
Chaplain.

and saddle, and to supply the place of the academy saddles, which have no stirrups to them.

CHAPELLE (Claudius Emanuel Luillier), the natural son of Francis Luillier, took the name of *Chapelle* from a village between Paris and St Denys, where he was born. He distinguished himself by writing small pieces of poetry, in which he discovered great delicacy, an easy turn, and an admirable facility of expression. He was the friend of Gassendi and Moliere; and died in 1686.

CHAPERON, CHAPERONNE, or CHAPEROON, properly signifies a sort of hood or covering of the head anciently worn both by men and women, the nobles and the populace, and afterwards appropriated to the doctors, and licentiates in colleges, &c. Hence the name passed to certain little shields, and other funeral devices, placed on the foreheads of the horses that drew the hearses in pompous funerals, and which are still called *chaperoons*, or *shafferoons*; because such devices were originally fastened on the *chaperonnes*, or hoods, worn by those horses with their other coverings of state.

CHAPERON of a bit-mouth, in the manege, is only used for scatch-mouths, and all others that are not cannon-mouths, signifying the end of the bit that joins to the branch just by the banquet. In scatch-mouths the chaperon is round, but in others it is oval: and the same part that in scatch and other mouths is called *chaperon*, is in cannon-mouths called *froncedu*.

CHAPITERS, in architecture, the same with CAPITALS.

CHAPITERS, in law, formerly signified a summary of such matters as were inquired of, or presented before justices in eyre, justices of assize, or of the peace in their sessions.

Chapiters, at this time, denote such articles as are delivered by the mouth of the justice in his charge to the inquest.

CHAPLAIN properly signifies a person provided with a chapel; or who discharges the duty thereof.

CHAPLAIN is also used for an ecclesiastical person, in the house of a prince, or a person of quality, who officiates in their chapels, &c.

In England there are 48 chaplains to the king, who wait four each month, preach in the chapel, read the service to the family, and to the king in his private oratory, and say grace in the absence of the clerk of the closet. While in waiting they have a table, and attendance, but no salary. In Scotland the king has six chaplains, with a salary of L. 50 each, three of them having in addition the deanery of the chapel-royal divided between them, making up above L. 100 to each. Their only duty at present is to say prayers at the election of peers for Scotland to sit in parliament. — According to a statute of Henry VIII. the persons vested with a power of retaining chaplains, together with the number each is allowed to qualify, is as follows: An archbishop, eight; a duke or bishop, six; marquis or earl, five; viscount, four; baron, knight of the garter, or lord chancellor, three; a duchess, marchioness, countess, baroness, the treasurer and comptroller of the king's house, clerk of the closet, the king's secretary, dean of the chapel, almoner, and master of the rolls, each of them two; chief justice of the king's bench, and warden of the cinque-

ports, each one. All these chaplains may purchase a licence or dispensation, and take two benefices with cure of souls. A chaplain must be retained by letters testimonial under hand and seal; for it is not sufficient that he serve as chaplain in the family.

The first chaplains are said to have been those instituted by the ancient kings of France, for preserving the chape, or cape, with the other relics of St Martin, which the kings kept in their palace, and carried out with them to the war. The first chaplain is said to have been Gul. de Mesmes, chaplain to St Louis.

CHAPLAIN in the order of Malta, is used for the second rank, or class, in that order; otherwise called *diaco*.

The knights make the first class, and the chaplains the second.

CHAPLAINS of the Pope, are the auditors, or judges of causes in the sacred palace; so called, because the pope anciently gave audience in his chapel, for the decision of cases sent from the several parts of Christendom. He hither summoned as assessors the most learned lawyers of his time; and they hence acquired the appellation of *capellani*, chaplains. It is from the decrees formerly given by these, that the body of decretals is composed: their number pope Sixtus IV. reduced to twelve.

Some say, the shrines of relics were covered with a kind of tent, cape, or *capella*, i. e. little cape; and that hence the priests, who had the care of them, were called chaplains. In time these relics were repositied in a little church, either contiguous to a larger, or separate from it; and the same name, *capella*, which was given to the cover, was also given to the place where it was lodged: and hence the priest who superintended it came to be called chaplain.

CHAPLET, an ancient ornament for the head, like a garland or wreath; but this word is frequently used to signify the circle of a crown. There are instances of its being borne in a coat of arms, as well as for crests; the paternal arms for Lascelles are argent, three chaplets, gules.

CHAPLET also denotes a string of beads used by the Roman Catholics, to count the number of their prayers. The invention of it is ascribed to Peter the hermit, who probably learned it of the Turks, as they owe it to the East-Indians.

Chaplets are sometimes called *pater-nosters*; and are made of coral, of diamonds, of wood, &c. The common chaplet contains fifty ave-marias, and five pater-nosters. There is also a chaplet of our Saviour, consisting of 33 beads, in honour of his 33 years living on earth, instituted by father Michael the Camaldusian.

The Orientals have a kind of chaplets which they call *chains*, and which they use in their prayers, rehearsing one of the perfections of God on each link or head. The Great Mogul is said to have 18 of these chains, all precious stones; some diamonds, others rubies, pearls, &c. The Turks have likewise chaplets, which they bear in the hand, or hang at the girdle: but father Dandini observes, they differ from those used by the Romanists, in that they are all of the same bigness, and have not that distinction into decads; though they consist of six decads, or 60 heads. He adds, that the mussulmans run over the chaplet almost in an instant, the prayers being extremely short, as containing only these words, "praise to God," or "glory"

Chaplain
||
Chaplet

Chaplet
||
Chapter.

"glory to God," for each bead. Besides the common chaplet they have likewise a larger one consisting of 100 beads, where there is some distinction, as being divided by little threads into three parts; on one of which they repeat 30 times *soubhan Allah*, i. e. "God is worthy to be praised;" on another, *ellamb Allah*, "glory be to God;" and on the third, *Allah echer*, "God is great." These thrice thirty times making only 90; to complete the number 100, they add other prayers for the beginning of the chaplet.—He adds, that the Mahometan chaplet appears to have had its rise from the *mea beracoth*, or "hundred benedictions;" which the Jews are obliged to repeat daily, and which we find in their prayer-books; the Jews and Mahometans having this in common, that they scarce do any thing without pronouncing some laud or benediction.

Menage derives the word *chaplet* from *chapeau*, "hat." The modern Latins call it *chapellina*, the Italians more frequently *corona*.

CHAPLET, or *Chapelet*, in architecture, a little moulding, cut, or carved into round beads, pearls, olives, or the like.

CHAPMAN (George), born in 1557, a man highly esteemed in his time for his dramatic and poetic works. He wrote 17 plays; translated Homer and some other ancient poets; and was thought no mean genius. He died in 1634; and was buried in St Giles's in the fields, where his friend Inigo Jones erected a monument to him.

CHAPPE', in heraldry, the dividing an escutcheon by lines drawn from the centre of the upper edge to the angles below, into three parts, the sections on the sides being of different metal or colour from the rest.

CHAPPEL IN FRITH, a market-town of Derbyshire, about 26 miles north-west of Derby; W. Long. 1. 50. N. Lat. 53. 22.

CHAPPEL (William) a learned and pious bishop of Cork, Cloyne, and Ross, in Ireland, born in Nottinghamshire in 1582. When the troubles began under Charles I. he was prosecuted by the puritan party in parliament, and retired to Derby, where he devoted himself to study until his death in 1649. He wrote *Methodus Concionandi*, i. e. "the method of preaching;" and he is one of those to whom the *Whole Duty of Man* has been attributed. He left behind him also his own life written by himself in Latin, which has been twice printed.

CHAPTER, in ecclesiastical polity, a society or community of clergymen belonging to the cathedrals and collegiate churches.

It was in the eighth century that the body of canons began to be called a chapter. The chapter of the canons of a cathedral were a standing council to the bishop, and, during the vacancy of the see, had the jurisdiction of the diocese. In the earlier ages, the bishop was head of the chapter; afterwards abbots and other dignitaries, as deans, provosts, treasurers, &c. were preferred to this distinction. The deans and chapters had the privilege of choosing the bishops in England; but Henry VIII. got this power vested in the crown: and as the same prince expelled the monks from the cathedrals, and placed secular canons in their room, those he thus regulated were called deans and chapters

of the new foundation; such are Canterbury, Winchester, Ely, Carlisle, &c. See DEAN.

CHAPTER, in matters in literature, a division in a book for keeping the subject treated of more clear and distinct.

CHAR, in ichthyology, a species of SALMO.

CHARA, in botany: A genus of the monandria order, belonging to the monœcia class of plants. There is neither male calyx nor corolla; and the anthera is placed under the germen. The female calyx is tetraphyllous; no corolla; the stigma quinquefid, with one roundish seed.

CHARABON, a sea-port town on the northern coast of the island of Java in the East-Indies; E. Long. 10. 8. S. Lat. 6.

CHARACENE, the most southern part of Susiana, a province of Persia, lying on the Persian gulph, between the Tigris and the Eulæus. It was so named from the city of Chorax, called first Alexandria, from its founder Alexander the Great; afterwards Antiochia, from Antiochus V. king of Syria, who repaired and beautified it; and lastly, Chorax Spasinæ, or Pafinæ, that is the Mole of the Spasines, an Arabian king of that name having secured it against the overflowing of the Tigris, by a high bank or mole, extending three miles, which served as a fence to all that country. Dionysius Periegetes, and Isidorus, author of the *Parthicæ Mansiones*, were both natives of this city. The small district of Characene was seized by Pafines, the son of Sogdonacus, king of the neighbouring Arabs, during the troubles of Syria, and erected into a kingdom. Lucian calls him Hyspafines, and adds, that he ruled over the Characeni and the neighbouring people: he died in the 85th year of his age. The other kings of this country we find mentioned by the ancients are, Teræus, who died in the 92d year of his age, and after him Artabazus the seventh, as Lucian informs us, who was driven from the throne by his own subjects, but restored by the Parthians. And this is all we find in the ancients relating to the kings of Characene.

CHARACTER, in a general sense, signifies a mark or figure, drawn on paper, metal, stone, or other matter, with a pen, graver, chissel, or other instrument, to signify or denote any thing. The word is Greek, *χαρακτηρ*, formed from the verb, *χαράσσειν*, *insculpere*, "to engrave, impress," &c.

The various kinds of characters may be reduced to three heads, viz. *Literal Characters*, *Numeral Characters*, and *Abbreviations*.

I. *LITERAL CHARACTER*, is a letter of the alphabet, serving to indicate some articulate sound, expressive of some idea or conception of the mind. See ALPHABET.

1. These may be divided, with regard to their nature and use, into *Nominal Characters*, or those we properly call *letters*; which serve to express the names of things: See LETTER. *Real Characters*; those that instead of names express things and ideas: See IDEA, &c. *Emblematical or Symbolical Characters*: which have this in common with real ones, that they express the things themselves; but have this further, that they in some measure personate them, and exhibit their form: such are the hieroglyphics of the ancient Egyptians. See HIEROGLYPHIC, SYMBOL, &c.

2. *LITERAL CHARACTERS* may be again divided, with regard

Chapter
||
Character.

Characters regard to their invention and use, into *particular* and *general* or *universal*.

Particular CHARACTERS, are those peculiar to this or that nation. Such are the Roman, Italic, Greek, Hebrew, Arabic, Gothic, Chinese, &c. *characters*. See HEBREW, GOTHIC, CHINESE, &c.

Universal CHARACTERS, are also *real characters*, and make what some authors call a *Philosophical Language*.

That diversity of *characters* used by the several nations to express the same idea, is found the chief obstacle to the advancement of learning: to remove this, several authors have taken occasion to propose plans of *characters* that should be universal, and which each people should read in their own language. The *character* here is to be real, not nominal: to express things and notions; not, as the common ones, letters or sounds: yet to be mute, like letters, and arbitrary; not emblematical, like hieroglyphics.

Thus, every nation should retain its own language, yet every one understand that of each other, without learning it; only by seeing a real or universal *character*, which should signify the same things to all people, by what sounds soever each expresses it in their particular idiom. For instance, by seeing the *character* destined to signify *to drink*, an Englishman should read *to drink*; a Frenchman, *boire*; a Latin, *bibere*; a Greek, *πιειν*; a Jew, *שׂוּמָה*; a German, *trincken*; and so of the rest: in the same manner as seeing a horse, each people expresses it after their own manner; but all mean the same animal.

This real *character* is no chimera; the Chinese and Japanese have already something like it. They have a common *character* which each of those nations understand alike in their several languages; though they pronounce them with such different sounds, that they do not understand one another in speaking.

The first and most considerable attempts for a *real character*, or philosophical language, in Europe, are those of bishop Wilkins and Dalgarno: but these, with how much art soever they were contrived, have yet proved ineffectual.

M. Leibnitz had some thoughts the same way; he thinks those great men did not hit the right method. It was probable, indeed, that by their means, people, who do not understand one another, might easily have a commerce together; but they have not hit on true *real characters*.

According to him, the *characters* should resemble those used in Algebra: which, in effect, are very simple, yet very expressive; without any thing superfluous or equivocal; and contain all the varieties required.

The *real character* of bishop Wilkins has its just applause: Dr Hook recommends it on his own knowledge and experience, as a most excellent scheme; and to engage the world to the study thereof, publishes some fine inventions of his own therein.

M. Leibnitz tells us, he had under consideration an *alphabet of human thoughts*; in order to a new philosophical language, on his own scheme: but his death prevented its being brought to maturity.

M. Lodwic, in the *philosophical transactions*, gives us a plan of an *universal alphabet* or *character* of another kind: this was to contain an enumeration of all such

Vol. IV. Part I.

single sounds, or letters, as are used in any language; *Characters*. by means whereof, people should be enabled to pronounce truly and readily any language; to describe the pronunciation of any language that shall be pronounced in their hearing, so as others accustomed to this language, though they had never heard the language pronounced, shall at first be able truly to pronounce it: and, lastly, this *character* to serve as a standard to perpetuate the sounds of any language. In the *Journal Litteraire*, an. 1720, we have a very ingenious project for an universal *character*. The author, after obviating the objections that might be made against the feasibility of such schemes in the general, proposes his own: his *characters* are to be the common Arabic, or numeral figures. The combinations of these nine are sufficient to express distinctly an incredible quantity of numbers, much more than we shall need terms to signify our actions, goods, evils, duties, passions, &c. Thus is all the trouble of framing and learning any new *character* at once saved; the Arabic figures having already all the universality required.

The advantages are immense. For, 1^{mo}, We have here a stable, faithful interpreter; [never to be corrupted or changed, as the popular languages continually are. 2^{do}, Whereas the difficulty of pronouncing a foreign language is such as usually gives the learner the greatest trouble, and there are even some sounds which foreigners never attain to; in the *character* here proposed, this difficulty has no place: every nation is to pronounce them according to the particular pronunciation that already obtains among them. All the difficulty is, the accustoming the pen and the eye to affix certain notions to *characters* that do not, at first sight, exhibit them. But this trouble is no more than we find in the study of any language whatever.

The inflections of words are here to be expressed by the common letters. For instance, the same *character* shall express a *filly* or a *colt*, a *horse* or a *mare*, an *old horse* or an *old mare*, as accompanied with this or that distinctive letter, which shall show the sex, youth, maturity, or old age: a letter also to express the bigness or size of things; thus *v. g.* a man with this or that letter, to signify a *great man*, or a *little man*, &c.

The use of these letters belongs to the grammar; which, once well understood, would abridge the vocabulary exceedingly. An advantage of this grammar is, that it would only have one declension and one conjugation: those numerous anomalies of grammarians are exceeding troublesome; and arise hence, that the common languages are governed by the populace, who never reason on what is best: but in the *character* here proposed, men of sense having the introduction of it, would have a new ground, whereon to build regularly.

But the difficulty is not in inventing the most simple, easy, and commodious *character*, but in engaging the several nations to use it; there being nothing they agree less in, than the understanding and pursuing their common interest.

3. Literal characters may again be divided, with respect to the nations among whom they have been invented, into Greek characters, Roman characters, Hebrew characters, &c. The Latin character now used through all Europe, was formed from the Greek, as the Greek was from the Phœnician; and the Phœnician,

Characters. as well as the Chaldee, Syriac, and Arabic characters, were formed from the ancient Hebrew, which subsisted till the Babylonish captivity; for after that event the character of the Assyrians, which is the square Hebrew now in use, prevailed, the ancient being only found on some Hebrew medals, commonly called Samaritan medals. It was in 1091 that the Gothic characters, invented by Ulphilas, were abolished, and the Latin ones established in their room.

Medallists observe, that the Greek character, consisting only of majuscule letters, has preserved its uniformity on all medals, as low as the time of Gallienus, from which time it appears somewhat weaker and rounder: from the time of Constantine to Michael we find only Latin characters: after Michael, the Greek characters recommence; but from that time they began to alter with the language, which was a mixture of Greek and Latin. The Latin medals preserve both their character and language as low as the translation of the feat of the empire to Constantinople: towards the time of Decius the character began to lose its roundness and beauty; some time after, it retrieved, and subsisted tolerably till the time of Justin, when it degenerated gradually into the Gothic. The rounder, then, and better formed a character is upon a medal, the fairer pretence it has to antiquity.

II. *Numeral CHARACTERS*, or characters used to express numbers, are either letters or figures.

The Arabic character, called also the common one, because it is used almost throughout Europe in all sorts of calculations, consists of these ten digits 1, 2, 3, 4, 5, 6, 7, 8, 9, 0.

The Roman numeral character consists of seven majuscule letters of the Roman alphabet, viz. I, V, X, L, C, D, M. The I denotes one, V five, X ten, L fifty, C a hundred, D five hundred, and M a thousand. The I repeated twice makes two, II; thrice, three, III: four is expressed thus IV, as I before V or X takes an unit from the number expressed by these letters. To express six, an I is added to a V, VI; for seven, two, VII; and for eight, three, VIII. nine is expressed by an I before X, thus IX. The same remark may be made of the X before L or C, except that the diminution is by tens; thus, XL denotes forty, XC ninety, and LX sixty. The C before D or M diminishes each by a hundred. The number five hundred is sometimes expressed by an I before a C inverted, thus, IC; and instead of M, which signifies a thousand, an I is sometimes used between two C's, the one direct, and the other inverted, thus CIC. The addition of C and I before or after raises CIC by tens, thus, CCIC expresses ten thousand, CCCIC, a hundred thousand. The Romans also expressed any number of thousands by a line drawn over any numeral less than a thousand; thus $\overline{V}$ denotes five thousand, $\overline{LX}$, sixty thousand: so likewise $\overline{M}$ is one million, $\overline{MM}$ is two millions, &c.

The Greeks had three ways of expressing numbers: 1. Every letter, according to its place in the alphabet, denoted a number, from α , one, to ω , twenty-four. 2. The alphabet was divided into eight units, α one, β two, three, &c.; into eight tens, ι ten, κ twenty, λ thirty, &c.; and eight hundreds, ρ one hundred, σ two hundred, τ three hundred, &c. 3. I stood for one, II five, Δ ten, H a hundred, X a thousand, M ten thousand; and when the letter II inclosed any of these,

except I, it showed the inclosed letter to be five times its value: as $\overline{\Delta I}$ fifty, $\overline{IH}$ five hundred, $\overline{IX}$ five thousand, $\overline{IM}$ fifty thousand.

The French CHARACTER used in the chamber of accounts, and by persons concerned in the management of the revenue, is, properly speaking, nothing else than the Roman numerals, in letters that are not majuscule: thus, instead of expressing fifty-six by LVI, they denote it by smaller characters lvj.

III. CHARACTERS of Abbreviations, &c. in several of the arts, are symbols contrived for the more concise and immediate conveyance of the knowledge of things. For the

CHARACTERS used in Algebra. See ALGEBRA, Introduction.

CHARACTERS used in Music, and of Musical Notes with their proportions, are as follow.

≡ character of a large	8	♩ crotchet	$\frac{1}{4}$
♩ a long	4	♪ quaver	$\frac{1}{8}$
♪ a breve	2	♩ semiquaver	$\frac{1}{16}$
♩ a semibreve	1	♪ demisemiquaver	$\frac{1}{32}$
♪ a minim	$\frac{1}{2}$		

✱ character of a sharp note: this character at the beginning of a line or space, denotes that all the notes in that line are to be taken a semitone higher than in the natural series; and the same affects all the octaves above and below, though not marked: but when prefixed to any particular note, it shows that note alone to be taken a semitone higher than it would be without such character.

b or b, character of a flat note: this is the contrary to the other above; that is, a semitone lower.

♮ character of a natural note: when in a line or series of artificial notes, marked at the beginning b or ✱, the natural note happens to be required, it is denoted by this character.

♯ character of the treble cliff.

♭ character of the mean cliff.

♮ bass cliff.

$\frac{2}{2}$, or $\frac{4}{4}$ characters of common duple time, signifying the measure of two crotchets to be equal to two notes, of which four make a semibreve.

C C P, characters that distinguish the movements

of common time, the first implying slow, the second quick, and the third very quick.

$\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{1}{8}$, $\frac{3}{16}$, characters of simple triple time, the measure of which is equal to three semibreves, or to three minims.

$\frac{4}{8}$, $\frac{6}{8}$, or $\frac{9}{8}$, characters of a mixed triple time, where the measure is equal to six crotchets, or six quavers.

$\frac{9}{8}$, or $\frac{6}{8}$, or $\frac{12}{8}$, or $\frac{1}{2}$, or $\frac{3}{4}$, characters of compound triple time.

$\frac{4}{12}$, $\frac{8}{12}$, $\frac{12}{12}$, or $\frac{1}{4}$, or $\frac{2}{4}$, characters of that species of triple time called the measure of twelve times.

CHARACTER, in human life, that which is peculiar in the manners of any person, and distinguishes him from all others.

Good CHARACTER is particularly applied to that conduct which is regulated by virtue and religion; in an inferior but very common sense, it is understood of mere honesty of dealing between man and man. The importance of a good character in the commerce of life seems to be universally acknowledged.—To those who are to make their own way either to wealth or honours, a good character is usually no less necessary than address and abilities. To transcribe the observation of an elegant moralist: Though human nature is degenerate, and corrupts itself still more by its own inventions; yet it usually retains to the last an esteem for excellence. But even if we are arrived at such an extreme degree of depravity as to have lost our native reverence for virtue; yet a regard to our own interest and safety, which we seldom lose, will lead us to apply for aid, in all important transactions, to men whose integrity is unimpeached. When we choose an assistant, a partner, a servant, our first enquiry is concerning his character. When we have occasion for a counsellor or attorney, a physician or apothecary, whatever we may be ourselves, we always choose to trust our property and persons to men of the best character. When we fix on the tradesmen who are to supply us with necessaries, we are not determined by the sign of the lamb, or the wolf, or the fox; nor by a shop fitted up in the most elegant taste, but by the fairest reputation. Look into a daily newspaper, and you will see, from the highest to the lowest rank, how important the characters of the employed appear to the employers. After the advertisement has enumerated the qualities required in the person wanted, there constantly follows, that none need apply who cannot bring an undeniable character. Offer yourself as a candidate for a seat in parliament, be promoted to honour and emolument, or in any respect attract the attention of mankind upon yourself, and, if you are vulnerable in your character, you will be deeply wounded. This is a general testimony in favour of honesty, which no writings and no practices can possibly refute.

Young men, therefore, whose characters are yet unfixed, and who, consequently, may render them just such as they wish, ought to pay great attention to the first steps which they take on entrance into life. They are usually careless and inattentive to this object. They pursue their own plans with ardour, and neglect the opinions which others entertain of them. By some thoughtless action or expression, they suffer a mark to be impressed upon them, which scarcely any subsequent merit can entirely erase. Every man will find some persons,

Character. fons, who, though they are not professed enemies, yet view him with an envious or a jealous eye, and who will gladly revive any tale to which truth has given the slightest foundation.

In this turbulent and confused scene, where our words and actions are often misunderstood, and oftener misrepresented, it is indeed difficult even for innocence and integrity to avoid reproach, abuse, contempt, and hatred. These not only hurt our interest and impede our advancement in life, but sorely afflict the feelings of a tender and delicate mind. It is then the part of wisdom first to do every thing in our power to preserve an irreproachable character, and then to let our happiness depend chiefly on the approbation of our own consciences, and on the advancement of our interest in a world where liars shall not be believed, and where slanderers shall receive countenance from none but him who, in Greek, is called, by way of eminence, *Diabolus*, or the calumniator.

CHARACTER, in poetry, particularly the epopee and drama, is the result of the manners or peculiarities by which each person is distinguished from others.

The poetical character, says Mr Bosiu, is not properly any particular virtue or quality, but a composition of several which are mixed together, in a different degree, according to the necessity of the fable and the unity of the action: there must be one, however, to reign over all the rest; and this must be found, in some degree, in every part. The first quality in Achilles, is wrath; in Ulysses, dissimulation; and in Æneas, mildness: but as these characters cannot be alone, they must be accompanied with others to embellish them, as far as they are capable, either by hiding their defects, as in the anger of Achilles, which is palliated by extraordinary valour; or by making them centre in some solid virtue, as in Ulysses, whose dissimulation makes a part of his prudence; and in Æneas, whose mildness is employed in a submission to the will of the gods. In the making up of which union, it is to be observed, the poets have joined together such qualities as are by nature the most compatible; valour with anger, piety with mildness, and prudence with dissimulation. The fable required prudence in Ulysses, and piety in Æneas; in this, therefore, the poets were not left to their choice: but Homer might have made Achilles a coward without abating any thing from the justness of his fable: so that it was the necessity of adorning his character that obliged him to make him valiant: the character, then, of a hero in the epic poem, is compounded of three sorts of qualities; the first essential to the fable; the second, embellishments of the first; and valour, which sustains the other two, makes the third.

Unity of character is as necessary as the unity of the fable. For this purpose a person should be the same from the beginning to the end: not that he is always to betray the same sentiments, or one passion; but that he should never speak nor act inconsistently with his fundamental character. For instance, the weak may sometimes fall into a warmth, and the breast of the passionate be calm, a change which often introduces in the drama a very affecting variety; but if the natural disposition of the former was to be represented as boisterous, and that of the latter mild and soft, they would both act out of character, and contradict their persons.

True characters are such as we truly and really see in men, or may exist without any contradiction to nature: no man questions but there have been men as generous and as good as Æneas, as passionate and as violent as Achilles, as prudent and wise as Ulysses, as impious and atheistical as Mezentius, and as amorous and passionate as Dido; all these characters, therefore, are true, and nothing but just imitations of nature. On the contrary, a character is false when an author so feigns it, that one can see nothing like it in the order of nature wherein he designs it shall stand: these characters should be wholly excluded from a poem, because transgressing the bounds of probability and reason, they meet with no belief from the readers; they are fictions of the poet's brain, not imitations of nature; and yet all poetry consists in an imitation of nature.

CHARACTER is also used for certain visible qualities, which claim respect or reverence to those vested therewith.—The majesty of kings gives them a character which procures respect from the people. A bishop should sustain his character by learning and solid piety, rather than by worldly lustre, &c. The law of nations secures the character of an ambassador from all insults.

CHARACTER, among naturalists, is synonymous with the definition of the genera of animals, plants, &c.

CHARACTERISTIC, in the general, is that which characterises a thing or person, i. e. constitutes its character, whereby it is distinguished. See **CHARACTER**.

CHARACTERISTIC, is peculiarly used in grammar, for the principal letter of a word: which is preserved in most of its tenses and moods, its derivatives and compounds.

CHARACTERISTIC of a Logarithm, is its index or exponent. See **LOGARITHM**.

CHARACTERISTIC Triangle of a Curve, in the higher geometry, is a rectilinear right-angled triangle, whose hypotenuse makes a part of the curve, not sensibly different from a right line. It is so called, because curve lines are used to be distinguished hereby. See **CURVE**.

CHARADE, the name of a new species of composition or literary amusement. It owes its name to the idler who invented it. Its subject must be a word of two syllables, each forming a distinct word; and these two syllables are to be concealed in an enigmatical description, first separately, and then together. The exercise of charades, if not greatly instructive, is at least innocent and amusing. At all events, as it has made its way into every fashionable circle, and has employed even Garrick, it will scarcely be deemed unworthy of attention. The filliness indeed of most that have appeared in the papers under this title, are not only destitute of all pleasantry in the stating, but are formed in general of words utterly unfit for the purpose. They have therefore been treated with the contempt they deserved. In trifles of this nature, inaccuracy is without excuse. The following examples therefore are at least free from this blemish.

I.

My first, however here abused,
Designs the sex alone;
In Cambria, such is custom's pow'r,
'Tis Jenkin, John, or Joan.

My

Character
||
Charade.

Charade,
Charadrius.

My *second* oft is loudly call'd,
When men prepare to fist it;
Its name delights the female ear;
Its force, may none resist it!
It binds the weak, it binds the strong,
The wealthy and the poor;
Still 'tis to joy a passport deem'd,
For sullied fame a cure.
It may insure an age of bliss,
Yet mis'ries oft attend it;
To fingers, ears, and noses too,
Its various lords commend it.
My *whole* may chance to make one drink,
Though vend'd in a fish-shop;
'Tis now the monarch of the seas,
And has been an archbishop.

Her-ring.

II.

My *first*, when a Frenchman is learning English,
serves him to swear by. My *second*, is either hay or
corn. My *whole*, is the delight of the present age,
and will be the admiration of posterity. Gar-rick.

III.

My *first*, is plowed for various reasons, and grain
is frequently buried in it to little purpose. My *se-*
cond, is neither riches nor honours; yet the former
would generally be given for it, and the latter is often
tasteless without it. My *whole* applies equally to spring,
summer, autumn, and winter; and both fish and flesh,
praise and censure, mirth and melancholy, are the
better for being in it. Sea-son.

IV.

My *first*, with the most rooted antipathy to a French-
man, prides himself, whenever they meet, upon stick-
ing close to his jacket. My *second* has many virtues,
nor is it its least that it gives name to my first. My
whole, may I never catch! Tar-tar.

V.

My *first* is one of England's prime boasts; it re-
joices the ear of a horse, and anguishes the toe of a
man. My *second*, when brick, is good; when stone,
better; when wooden, best of all. My *whole* is famous
alike for rottenness and tin. Corn-wall.

VI.

My *first* is called bad or good,
May pleasure or offend ye;
My *second*, in a thirsty mood,
May very much befriend ye.
My *whole*, tho' styled a "cruel word,"
May yet appear a kind one;
It often may with joy be heard,
With tears may often blind one. Fare-well.

VII.

My *first* is equally friendly to the thief and the lover,
the toper and the student. My *second* is light's oppo-
site: yet they are frequently seen hand in hand; and
their union, if judicious, gives much pleasure. My
whole, is tempting to the touch, grateful to the sight,
fatal to the taste. Night-shade.

CHARADRIUS, in ornithology, a genus belong-
ing to the order of grallæ. The beak is cylindrical and
blunt; the nostrils are linear; and the feet have three
toes.

1. The Hiaticula, or Sea-lark of Ray, has a black
breast; a white streak along the front; the top of the
head is brown; and the legs and beak are reddish. It
is found on the shores of Europe and America. They

frequent our shores in the summer, but are not nume-
rous. They lay four eggs, of a dull whitish colour,
sparingly sprinkled with black: at the approach of win-
ter they disappear.

2. The Alexandrinus, or Alexandrian Dotterel, is
of a brownish colour, with the forehead, collar, and
belly white; the prime tail-feathers on both sides are
white; and the legs are black. It is about the size of
a lark, and lives upon insects.

3. The Vociferus, or Noisy Plover of Catesby, has
black streaks on the breast, neck, forehead, and cheeks;
and the feet are yellow. It is a native of North Ame-
rica.

4. The Ægyptius has a black streak on the breast,
white eye-brows, the prime tail-feathers streaked with
black at the points, and bluish legs. It is found in the
plains of Egypt, and feeds on insects.

5. The Morinellus has an iron-coloured breast, a
small white streak on the breast and eye-brows, and
black legs. It is the Dotterel of Ray, and a native
of Europe. They are found in Cambridgeshire, Lin-
colnshire, and Derbyshire: on Lincoln-heath, and on
the moors of Derbyshire, they are migratory; appear-
ing there in small flocks of eight or ten only in the lat-
ter end of April, and stay there all May and part of
June, during which time they are very fat, and much
esteemed for their delicate flavour. In the months of
April and September, they are taken on the Wiltshire
and Berkshire downs: they are also found in the be-
ginning of the former month on the sea-side at Meales
in Lancashire, and continue there about three weeks,
attending the barley fallows: from thence they re-
move northward to a place called Leyton Haws, and
stay there about a fortnight; but where they breed,
or where they reside during the winter, we have not
been able to discover. They are reckoned very fool-
ish birds, so that a dull fellow is proverbially styled a
dotterel. They were also believed to mimic the action
of the fowler, stretching out a wing when he stretches
out an arm, &c. continuing their imitation, regardless
of the net that is spreading for them.

6. The Apricarius has a black belly; the body is
brown, and variegated with white and yellow spots;
and the legs are ash-coloured. It is the spotted Plover
of Edwards, and a native of Canada.

7. The Pluvialis is black above, with green spots,
white underneath, and the feet are ash-coloured. It
is the green plover of Ray, and is a native of Europe.
They lay four eggs, sharply pointed at the lesser end,
of a dirty white colour, and irregularly marked, espe-
cially at the thicker end, with blotches and spots. It
breeds on several of our unfrequented mountains;
and is very common on those of the isle of Rum, and
others of the loftier Hebrides. They make a shrill
whistling noise; and may be enticed within a shot by
a skilful imitator of the note.

8. The Torquatus has a black breast, and a white
front; the top of the head and the collar is black;
and the beak and feet are bluish. It is a native of St
Domingo.

9. The Calidris has black feet, and a black bill; the
rump is greyish; and the body is pure white below.
It frequents the shores of Europe.

10. The Œdicnemus or Stone-curlew of Ray, is of
a grey colour, with two of the prime wing-feathers
black, but white in the middle: it has a sharp bill,
and

Charadrius and ash-coloured feet; and is about the size of a crow. In Hampshire, Norfolk, and on Lincoln-heath, it is called the stone-curlew, from a similarity of colours to the curlew. It breeds in some places in rabbit-burrows; also among stones on the bare ground, laying two eggs of a copper-colour spotted with a darker red. The young run soon after they are hatched. These birds feed in the night on worms and caterpillars: they will also eat toads, and will catch mice. They inhabit fallow lands and downs; affect dry places, never being seen near any waters. When they fly, they extend their legs straight out behind: are very shy birds; run far before they take to wing; and often squat: are generally seen single; and are esteemed very delicate food.—Hasselquist informs us, that this bird is also met with in Lower Egypt, in the Acacia groves, near the villages Abusir and Sackhara, near the sepulchres of the ancient Egyptians, and in the deserts. The Arabians call it Kervan. It has a shrill voice, somewhat resembling that of the black woodpecker, which it raises and lowers successively, uttering agreeable notes. The Turks and Egyptians value it much, if they can get it alive; and keep it in a cage for the sake of its singing. Its flesh is hard, and of a very good taste, inclined to aromatic. It is a very voracious bird, catching and devouring rats and mice, which abound in Egypt. It seldom drinks; and when taken young, and kept in a cage in Egypt, they give it no water for several months, but feed it with fresh meat macerated in water, which it devours very greedily. It is found in deserts, and is therefore accustomed to be without water.

11. The Himantopus is white below, with a black back, and a long black bill; the feet are red, and very long. It is the autumnal dotterel of the English authors, and frequents the sea-shores of Europe. It is also found in the lakes of Egypt in the month of October.

12. The Spinofus, armed Dotterel, or Lapwing, has black breast, legs, and wings; it has a crest on the hinder part of the head. It is of the size of a pigeon; the French call it *dominicanus*, from the resemblance it has to the dress of a Dominican monk. It is a native of Egypt.

13. The New-Zealand plover, has the forepart of the head, taking in the eye, chin, and throat, black, passing backwards in a collar at the hind head; all the back part of the head, behind the eye, greenish ash-colour; these two colours divided by white: the plumage on the upper parts of the body is the same colour as the back of the head: the quills and tail are dusky: the last order of coverts is white for some part of their length, forming a bar on the wing: the under parts of the body are white; and the legs red. It inhabits Queen Charlotte's sound; where it is known by the name of *Doodooroa-attoo*. See Plate CXXII. There are 12 or 13 more species.

CHARAG, the tribute which Christians and Jews pay to the grand signior.

It consists of ten, twelve, or fifteen francs *per annum*, according to the estate of the party. Men begin to pay it at nine or at sixteen years old; women are dispensed with, as also priests, rabbins, and religious.

CHARAIMS, a sect of the Jews in Egypt. They live by themselves, and have a separate synagogue;

and as the other Jews are remarkable for their eyes, so are those for their large noses, which run through all the families of this sect. These are the ancient Essenes. They strictly observe the five books of Moses, according to the letter; and receive no written traditions. It is said that the other Jews would join the *Charaims*; but those not having observed the exact rules of the law with regard to divorces, these think they live in adultery.

CHARANTIA, in botany. See MOMORDICA.

CHARBON, in the manege, that little black spot or mark which remains after a large spot in the cavity of the corner teeth of a horse: about the seventh or eighth year, when the cavity fills up, the tooth being smooth and equal, it is said to be rased.

CHARCAS, the southern division of Peru in South America, remarkable for the silver mines of Potosi.

CHARCOAL, a sort of artificial coal, or fuel, consisting of wood half burnt; chiefly used where a clear strong fire, without smoke, is required; the humidity of the wood being here mostly dissipated, and exhaled in the fire wherein it is prepared.

The microscope discovers a surprising number of pores in charcoal: they are disposed in order, and traverse it lengthwise; so that there is no piece of charcoal, how long soever, but may be easily blown through. If a piece be broken pretty short, it may be seen through with a microscope. In a range the 18th part of an inch long, Dr Hook reckoned 150 pores; whence he concludes, that in a charcoal of an inch diameter, there are not less than 5,724,000 pores. It is to this prodigious number of pores, that the blackness of charcoal is owing: for the rays of light striking on the charcoal, are received and absorbed in its pores, instead of being reflected; whence the body must of necessity appear black, blackness in a body being no more than a want of reflection. Charcoal was anciently used to distinguish the bounds of estates and inheritances; as being incorruptible, when let very deep within ground. In effect, it preserves itself so long, that there are many pieces found entire in the ancient tombs of the northern nations. M. Dodart says, there is charcoal made of corn, probably as old as the days of Cæsar: he adds, that it has kept so well, that the wheat may be still distinguished from the rye; which he looks on as proof of its incorruptibility.

The operation of charring wood, is performed in the following manner: The wood intended for this purpose is cut into proper lengths, and piled up in heaps near the place where the charcoal is intended to be made: when a sufficient quantity of wood is thus prepared, they begin constructing their stacks, for which there are three methods. The first is this: They level a proper spot of ground, of about twelve or fifteen feet in diameter, near the piles of wood; in the centre of this area a large billet of wood, split across at one end and pointed at the other, is fixed with its pointed extremity in the earth, and two pieces of wood inserted through the clefts of the other end, forming four right-angles; against these cross pieces four other billets of wood are placed, one end on the ground, and the other leaning against the angles. This being finished, a number of large and straight billets

Charantia
||
Charcoal.

Charcoal. Billets are laid on the ground to form a floor, each being as it were the radius of the circular area: on this floor a proper quantity of brush or small wood is strewed, in order to fill up the interstices, when the floor will be complete; and in order to keep the billets in the same order and position in which they were first arranged, pegs or stumps are driven into the ground in the circumference of the circle, about a foot distant from one another: upon this floor a stage is built with billets set upon one end, but something inclining towards the central billet; and on the tops of these another floor is laid in a horizontal direction, but of shorter billets, as the whole is, when finished, to form a cone.

The second method of building the stacks for making charcoal is performed in this manner: A long pole is erected in the centre of the area above described, and several small billets ranged round the pole on their ends: the interstices between these billets and the pole is filled with dry brush-wood, then a floor is laid, on that a stage in a reclining position, and on that a second floor, &c. in the same manner as described above; but in the lower floor there is a billet larger and longer than the rest, extending from the central pole to some distance beyond the circumference of the circle.

The third method is this: A chimney, or aperture of a square form, is built with billets in the centre, from the bottom to the top; and round these, floors and inclined stages are erected, in the same manner as in the stacks above described, except that the base of this, instead of being circular like the others, is square; and the whole stack, when completed, forms a pyramid.

The stack of either form being thus finished, is coated over with turf, and the surface plastered with a mixture of earth and charcoal-dust well tempered together.

The next operation is the setting the stack on fire. In order to this, if it be formed according to the first construction, the central billet in the upper stage is drawn out, and some pieces of very dry and combustible wood are placed in the void space, called, by workmen, the chimney, and fire set to these pieces. If the stack be built according to the second construction, the central pole is drawn out, together with the large horizontal billet above described; and the void space occupied by the latter being filled with pieces of very dry combustible wood, the fire is applied to it at the base of the stack. With regard to the third construction, the square aperture or chimney is filled with small pieces of very dry wood, and the fire applied to it at the top or apex of the pyramidal stack. When the stack is set on fire, either at the top or bottom, the greatest attention is necessary in the workman; for in the proper management of the fire the chief difficulty attending the art of making good charcoal consists. In order to this, care is taken, as soon as the flame begins to issue some height above the chimney, that the aperture be covered with a piece of turf, but not so close as to hinder the smoke from passing out; and whenever the smoke appears to issue very thick from any part of the pile, the aperture must be covered with a mixture of earth and charcoal dust. At the same time, as it is necessary that every part of the stack should be equally burnt, it will be requisite for

the workman to open vents in one part and shut them in another. In this manner the fire must be kept up till the charcoal be sufficiently burnt, which will happen in about two days and a half, if the wood be dry; but if green, the operation will not be finished in less than three days. When the charcoal is thought to be sufficiently burnt, which is easily known from the appearance of the smoke, and the flames no longer issuing with impetuosity through the vents; all the apertures are to be closed up very carefully with a mixture of earth and charcoal-dust, which, by excluding all access of the external air, prevents the coals from being any further consumed, and the fire goes out of itself. In this condition it is suffered to remain, till the whole is sufficiently cooled; when the cover is removed, and the charcoal is taken away. If the whole process is skilfully managed, the coals will exactly retain the figure of the pieces of wood: some are said to have been so dexterous as to char an arrow without altering even the figure of the feather.

There are considerable differences in the coals of different vegetables, in regard to their habitude to fire: the very light coals of linen, cotton, some fungi, &c. readily catch fire from a spark, and soon burn out; the more dense ones of woods and roots are set on fire more difficultly, and burn more slowly: the coals of the black berry-bearing alder, of the hazel, the willow, and the lime-tree, are said to answer best for the making of gunpowder and other pyrotechnical compositions, perhaps from their being easily inflammable: for the reduction of metallic calces those of the heavier woods, as the oak and the beech, are preferable, these seeming to contain a larger proportion of the phlogistic principle, and that, perhaps, in a more fixed state: considered as common fuel, those of the heavy woods give the greatest heat, and require the most plentiful supply of air to keep them burning; those of the light woods preserve a glowing heat, without much draught of air, till the coals themselves are consumed; the bark commonly crackles and flies about in burning, which the coal of the wood itself very seldom does.

Mathematical-instrument makers, engravers, &c. find charcoal of great use to polish their brass and copper-plates after they have been rubbed clean with powdered pumice-stone. Plates of horn are polishable in the same way, and a gloss may be afterwards given with tripoli.

The coals of different substances are also used as pigments; hence the bone-black, ivory-black, &c. of the shops. Most of the paints of this kind, besides their incorruptibility, have the advantage of a full colour, and work freely in all the forms in which powdery pigments are applied; provided they have been carefully prepared, by thoroughly burning the subject in a close vessel, and afterwards grinding the coal into a powder of due fineness. Pieces of charcoal are used also in their entire state for tracing the outlines of drawings, &c.; in which intention they have an excellence, that their mark is easily wiped out. For these purposes, either the finer pieces of common charcoal are picked out and cut to a proper shape; or the pencils are formed of wood, and afterwards burnt into charcoal in a proper vessel well covered. The artists commonly make choice of the smaller branches of the tree freed from the bark and pith; and the willow and vine

Charcoal.
Philosoph.
Commerce of
Arts.

vine are preferred to all others. This choice is confirmed by the experiments of Dr Lewis, who has found that the wood of the trunks of trees produces charcoal of a harder nature than their small twigs or branches; and the hard woods, such as box and guaiacum, produced coals very sensibly harder than the softer woods. Willow he prefers to all others. The shells and stones of fruits yielded coals so hard that they would scarce mark on paper at all; while the coals of the kernels of fruits were quite soft and mellow. The several coals produced by the doctor's experiments were levigated into fine powder, mixed both with gum-water and oil, and applied as paints both thin and thick, and diluted with different degrees of white. All of them, when laid on thick, appeared of a strong full black, nor could it be judged that one was of a finer colour than another; diluted with white, or when spread thin, they had all somewhat of a bluish cast.

Horns and the bones, both of fishes and land animals, gave coals rather glossier and deeper-coloured than vegetables; and which, in general, were very hard, so as difficultly, or not at all, to stain paper. Here also the hardness of the coal seemed to depend on that of the subject from whence it was prepared; for silk, woollen, leather, blood, and the fleshy parts of animals, yielded soft coals. Some of these differed from others very sensibly in colour: that of ivory is superior to all the rest, and indisputably the finest of all the charcoal blacks. The animal coals had much less of the bluish cast in them than the vegetable, many of them inclining rather to a brown. Charred pit-coal, on the other hand, seemed to have this blueness in a greater degree.

Charcoal is not soluble in any of the acids; but may be dissolved in considerable quantities by a solution of *hepar sulphuris*, to which it communicates a green colour. Melted with colourless frits or glasses, it gives a pale yellow, dark yellow, reddish, brownish, or blackish colour, according as the inflammable matter is in greater or less proportion; the phlogiston, or inflammable matter of the coal seeming to be the direct tinging substance. When the phlogistic matter is thus diffused through glass, it is no more affected by continued strong fire than charcoal is when excluded from the air.

The vapour of burning charcoal is found to be highly noxious, being no other than *fixed air*. How this affects the animal system is explained under the article **BLOOD**.

From some late experiments it appears, that charcoal possesses many extraordinary properties altogether unsuspected by former chemists. It has particularly a great attraction for what is called the *phlogiston*, or rather for any kind of oily matter with which other substances may be sullied; so that it now promises to be very useful in the arts in various ways never thought of before. M. Lowitz has found that it is useful in preparing crystals of tartar of a very white colour; and that the marine and nitrous acids are decomposed by being distilled upon it: the red juices of vegetable fruits are discoloured, without losing any of their acidity; brown rancid oils are rendered sweet and clear by agitating them for some days with charcoal in powder; it changes the smell of putrid vegetables to that of a pure volatile alkali, and it produces the same effect on fresh

Nº 69.

meat. On boiling coals in powder with honey, the pure saccharine parts of the latter are said to be separated, and the honey to become a well-tasted sugar; the purification of real sugar is also said to be facilitated by the same method. Thus also the mother-water of the Prussian alkali and of the tartareous acid are made to crystallize easily; *terra foliata tartari* may be made white without calcination, by previously distilling the vinegar from coals. Vinegar concentrated by freezing, and distilled from a large proportion of powdered coal, is extremely strong, pure, and fragrant. Corn spirit merely shaken with coal loses its bad flavour; and if honey is added, it becomes a sweet and pleasant liquor. Even when ardent spirits are impregnated with any vegetable oils, the flavour is destroyed in this way; and if the spirit be distilled, the residuum is said not to be brown; so that if the distillation is carried too far, no inconvenience ensues. With Peruvian bark a clear decoction was formed, and the residuum was a salt, in taste like digestive salt. These effects were produced by every kind of coal, whether fossil or charred vegetable substances.

Charcoal has lately been separated from the purest spirit of wine in the process for making ether*; and by M. Lavoisier is supposed to be one of the constituent parts or elements of that very volatile liquid. But the most extraordinary modern discovery concerning this substance is that of Dr Priestley, who has found that several of the metals may be converted into charcoal by passing the steam of spirit of wine over them when red-hot; and this, by way of distinction, he calls the *charcoal of metals*. * See Chemistry, Index.

This surprising discovery was made accidentally, while the Doctor was repeating the experiments by which M. Lavoisier imagined water might be converted into air. Having transmitted the steam of water thro' a copper tube, on which it had no effect, he was willing to try the effects of that of other fluids; and for this purpose made choice of spirit of wine, having before procured inflammable air by sending the same steam through a red-hot tobacco-pipe. No sooner had the vapour of this fluid, however, touched the red-hot copper, than he was astonished at the rapid production of air from it, which resembled the blowing of a pair of bellows; and before four ounces of the spirit were expended, the tube was found to be perforated in two or three places. In a moment afterwards it was so far destroyed, that it fell to pieces on attempting to remove it from the fire; the inside being filled with a black matter resembling lamp-black. Having now recourse to earthen tubes, the Doctor found that, by melting copper and other metals in them, and transmitting the vapour of spirit of wine in contact with them while in a state of ignition, different substances were formed according to the metals employed. On sending three ounce-measures of spirit of wine over two ounces of copper, the metal lost 28 grains of its weight, and 446 grains of charcoal were procured, chiefly in the form of powder, though some of it was in large flakes several inches long; having separated at once from the surface of the melted metal. These pieces were almost quite black, and bore handling without any danger of being broken. In another experiment, 508 grains of charcoal were obtained from 19 grains of copper; but here the metal had been previously reduced

Charcoal. duced to thin plates, and they were not all converted into charcoal, being something harder, and therefore partially metallic in the middle.

Silver was found to be affected very much as copper had been; but the larger masses of charcoal procured from this metal were much whiter than those from copper. Only a small quantity of charcoal could be procured from lead. Three ounce-measures of spirit of wine and near four ounces of lead, gave only a small quantity of whitish powdery substance, though 58 grains of the lead were missing; but the inside of the glass-tube through which the air was transmitted became very black. The like quantity of spirit of wine sent over 360 grains of melted tin, and produced 26 grains of black dust, the metal not being diminished quite four grains. The vapour of two ounce-measures of spirit of wine, sent over 960 grains of iron-shavings, diminished the metal only two grains; but no charcoal could be collected, though the air was loaded with black particles. The iron had acquired a dark blue colour. Gold was not sensibly changed or diminished in weight; and it not only remained unalterable by the process itself, but effectually protected a tenth-part of its weight of copper from the action of the steam.

Spirit of turpentine was found to answer for the production of this charcoal, as well as spirit of wine; 120 grains of the former being obtained from five of copper by means of the turpentine, notwithstanding a very dense black smoke which issued from the end of the tube during the whole time of the operation. The Doctor observes, indeed, that in all those experiments, where the heat is very great, the minute division and volatility of this charcoal is very extraordinary. Seeing it issue from the end of a tube in a dense black cloud, he endeavoured to collect it in a large glass receiver; but after having given the glass a very thin black coating, not distinguishable in appearance from soot, it issued from the orifice like dense smoke, and appeared to be altogether incoercible, even when several adopters were connected with the receiver, and a tube, from whence it finally issued, plunged deep into water.

It is observed, that charcoal of wood, when fresh made, has a strong attraction for air, and will continue to absorb it for a considerable time; a property which it has in common with several other substances. Dr Priestley made some experiments to ascertain the quantity absorbed. For this purpose, he left in an open dish, on the fourth of September, some charcoal fresh made from dry oak, and weighing 364 grains. Two or three days after it weighed 390 grains; on the 24th of October, 419; and on the 26th of April following it weighed 421 grains. By distillation in an earthen retort it yielded a quantity of air considerably phlogisticated, and then weighed 312 grains, but the retort appeared to have been cracked. On exposing it again to the open air for a whole year, it weighed 371 grains. In another experiment, a quantity of charcoal which had yielded by a strong heat 336 ounce-measures of air, and weighed immediately afterwards 756 grains, increased in three days to 817; and on expelling the air from it was reduced to 711 grains. In all these experiments the air was worse than that of the atmosphere, and a part was fixed air.

It has been generally supposed by chemists, that

VOL. IV. Part I.

charcoal was indestructible by any other means than burning in an open fire, though of late it is found totally dissipable and convertible into inflammable air, by the heat of a burning lens *in vacuo*, at least with the assistance of a small quantity of water. By burning in dephlogisticated air, it is found to convert almost the whole of it into fixed air. See AEROLOGY, n° 110—113, 129, 131. From the experiments there related, it is now evident, that charcoal as such, and without any decomposition, is an ingredient in both those aerial fluids, and is indeed the phlogiston of Stahl so long sought in vain. This discovery, however, has not by any means put an end to the disputes betwixt the *Phlogistians* and *Antiphlogistians*, though it certainly ought to have done so, and must assuredly do so in a short time. The experiments of Dr Priestley are not doubted; and charcoal, the gravitating matter of light inflammable air, and *phlogiston*, are allowed to be the same by the *Antiphlogistians* as well as by the opposite party. "The present controversy (says Mr Higgins) amongst philosophers depends upon the following questions: 1. Whether water be or be not composed of dephlogisticated and light inflammable air? 2. Whether or no the condensation of dephlogisticated air, or its union to different bodies, does not depend upon one principle, common to all combustible bodies? or, in other words, whether or no all bodies which burn or calcine, such as sulphur, phosphorus, charcoal, oils, metals, phlogisticated air, &c. contain the matter of light inflammable air as one of their constituent principles? One should suppose, if these substances were composed of two principles, namely a peculiar basis, and the matter of light inflammable air or phlogiston, that it would be possible to resolve them into these principles; more especially when we consider the great attraction of the matter of light inflammable air to fire; but the maintainers of phlogiston have not as yet been able to do this," &c.

The limits of this work will not allow us to enter on a full discussion of this controversy, nor can we pretend to be able to settle the disputes on the subject. It nevertheless seems somewhat unnatural to call iron, lead, copper, sulphur, phosphorus, &c. simple and unchangeable bodies, or if we please *elements*; as thus the number of elementary bodies might be increased without number, and *water*, which has generally been reckoned a simple one, supposed to be almost the only compound body in nature. It is also certain, that Dr Priestley has made some very striking and apparently decisive experiments on the subject of metals, to which no proper reply has ever been made. In order to see the force of these experiments, however, we must still observe, that, according to the *Phlogistians*, the calces of metals are reduced, on the addition of charcoal, not only by emitting the dephlogisticated air which adheres to them when in the form of calces, but by the admission of a quantity of the charcoal itself into their substance. This the *Antiphlogistians* deny; and though they admit the necessity of charcoal in the operation, yet they affirm that it acts only by attracting the dephlogisticated air contained in the calx, with which it forms fixed air; and hence they must say, that in all metallic reductions a quantity of fixed air is produced, equivalent not only to the weight of the charcoal employed, but also to that of the dephlogisticated air

Charcoal.

Higgins's
Comparative
View, Pref.
p. 5.

Charcoal. contained in the calx. The decisive experiment therefore would be, to expel from a metallic calx all the air it contained, to weigh it exactly in that state, and then observe whether it gained any thing in weight by being reduced to a metal. This, however, has not been done; and the Antiphlogistians complain that their adversaries have not been able to produce a pure metallic calx free from all kind of aerial vapour. But though it is not pretended that any such calx has yet been produced, if the Phlogistians can show the possibility of reducing a calx without the production of fixed air, it would seem to be equally destructive of the antiphlogistic doctrine. This appears to have been done by Dr Priestley in the experiments above alluded to; and it is even doubtful whether he did not obtain the so much desired calx, viz. one perfectly free from air altogether. "I put (says he) upon a piece of broken crucible, which could yield no air, a quantity of minium, out of which all air had been extracted; and placing it upon a convenient stand, introduced it into a large receiver filled with inflammable air confined by water. As soon as the minium was dry, by means of the heat thrown upon it, I observed that it became black, and then ran in the form of perfect lead, at the same time that the air diminished at a great rate the water ascending within the receiver. Before this first experiment was concluded, I perceived, that if the phlogiston in inflammable air had any base, it must be very inconsiderable; for the process went on till there was no more room to operate without endangering the receiver; and examining the air that remained, I found that it could not be distinguished from that in which I began the experiment, which was air extracted from iron by oil of vitriol.

"I afterwards carefully expelled, from a quantity of minium, all the phlogiston, and every thing else that could have assumed the form of air, by giving it a red heat when mixed with spirit of nitre; and immediately using it in the manner mentioned above, I reduced 101 ounce-measures of inflammable air to two. To judge of its degree of inflammability, I presented the flame of a small candle to the mouth of a vial filled with it, and observed, that it made 13 separate explosions, though weak ones (stopping the mouth of the phial with my finger after each explosion); when fresh made inflammable air, in the same circumstances, made only 14 explosions, though stronger ones. In this experiment, however, I overlooked one obvious consideration, viz. that water, or any thing soluble in water, might be the basis of inflammable air. All that could be absolutely inferred from the experiment was, that this basis could not be any thing that was capable of subsisting in the form of air. It will be seen, that I afterwards made the experiment with air confined by mercury."

In this experiment it is to be regretted that the Doctor did not inform us whether the weight of his calces was on the whole increased or diminished by the operation. As it stands, though sufficient to overthrow the doctrine of the Antiphlogistians, it is not altogether sufficient to establish that of their adversaries. Mr Higgins, however, though he does not reply to this experiment, gives an account of another from Dr Higgins, which he considers as absolutely decisive against the Phlogistians. "Dr Higgins (says he) in-

Charcoal. troduced some pieces of well-burned charcoal into a deep crucible, and covered them over an inch deep with powdered charcoal. Having luted on a cover, he exposed them for two hours to heat sufficient to melt silver; he then placed the crucible in such a manner that the powder might remain red hot for some time after the pieces next the bottom had cooled. This he had done, as the charcoal must imbibe something on cooling, both to supply it with inflammable air, and to prevent a communication with the external air, which the charcoal would otherwise have imbibed.

"One hundred and twenty grains of this charcoal quickly powdered, were well mixed with 7680 grains of litharge, which had been previously fused to separate any uncalcined lead it might contain. This mixture was charged into a coated retort just large enough to contain it; so that the common air must have been nearly secluded. Being then placed in a reverberating furnace, and heat duly applied, it yielded by estimation, after cooling to the mean temperature of the atmosphere, 384 grains of fixable air, at the rate of 0.57 grains to a cubic inch, 8.704 of phlogisticated air, and 0.911 grains of dephlogisticated air, besides 49 grains of water. On breaking the retort, 3888 grains of revived lead were found, besides some vitrified litharge; but not an atom of charcoal was left, nor was there a particle of inflammable air produced. Now, let my reader consider the weight that 3888 grains of lead acquire by its conversion to litharge, and the quantity of inflammable air that 120 grains of charcoal will afford (which, according to Dr Priestley, is about 360 ounce-measures), and he will find, making allowance for the phlogisticated air, that these nearly correspond with the proportion of heavy inflammable air and dephlogisticated air necessary to the formation of fixable air by the electric spark. Hence we may conclude, that not a particle of charcoal entered into the constitution of the revived lead, but must have been wholly converted into fixable air."

To this experiment, however, the Phlogistians will reply, that so far from being decisive on the subject, no conclusion whatever can be drawn from it, on account of its enormous inaccuracy. The quantity of matter put into the retort was $7680 + 120$, or 7800 grains, and the whole produce was $3888 + 384 + 8.704 + 0.911 + 49 = 4330.615$ grains: a deficiency therefore of no less than 3469.385 grains is to be accounted for; and of this we hear not one word; so that we are at liberty to suppose that the vitrified litharge had perforated the retort in such a manner as to admit the fixed and phlogisticated air from without, as Dr Priestley found earthen retorts pervious to air from without; and this, though coated, might by a corrosion of the glass (if it was a glass one) be reduced to a similar situation.

We do not mean that this should be reckoned a formal answer to Dr Higgins's experiment; all we intend here, is to state the arguments fairly on both sides, so that the reader who has not an opportunity of making experiments himself, may be able to judge on which side the truth lies. Dr Priestley informs us, that in his experiment, the calx of lead absorbed a quantity of inflammable air without the extrication of fixed air, or any thing else that could be perceived. Whether or not have we reason to conclude from thence,

Charcoal.

that the gravitating, solid, or coally, part of the inflammable air was received into the calx, and became part of the revived metal? In Dr Higgins's experiment a quantity of elastic fluid was produced, and a quantity of lead revived; but we neither know how much of the calx went to this lead, how much the litharge had originally attracted from the air, nor whether the elastic fluids were certainly produced; or indeed whether any of them, the small quantity of dephlogisticated air alone excepted, came from the materials or not. From such a state of the case then, have we reason to "conclude, that not a particle of charcoal entered into the constitution of the lead?"

Higgins's
Comparative
View, p. 49

We shall next consider an experiment made by Mr Higgins himself, and which he likewise considers as decisive against the Phlogistians. "I introduced (says he) some iron nails, free from rust, into strong volatile vitriolic acid; when it stood for a few minutes, it acquired a milky appearance, and the solution went on without ebullition or extrication of air. On standing for a few hours, the solution acquired a darkish colour, and a black powder was precipitated. This powder, when collected and washed, put on red hot iron, burned partly like sulphur and partly like charcoal dust, and the incombustible residuum was of a purplish colour. The filtered solution was perfectly neutralised, and free from the least sulphureous pungency. Its taste was strongly chalybeate, but not so disagreeable as that of the solution of iron in the perfect vitriolic acid, or in any of the mineral acids. Nitrous acid dropped into the solution instantly produced a cloudiness, which immediately disappeared without ebullition, though volatile sulphureous acid was extricated in its utmost degree of pungency. The vitriolic, marine, and acetous acids, decomposed this solution, but caused no turbidness, nor was any inflammable air produced.

"In order to know whether the sulphur was disengaged from the volatile sulphureous acid or the iron, I poured marine acid on the same nails, when light inflammable air and hepatic air were copiously produced, and likewise sulphur was deposited in its crude state. When I used vitriolic or the nitrous acid, no sulphur was produced. I tried different nails, and likewise iron-filings, with the same result. These facts convinced me that the sulphur came from the iron; but that all sorts of iron contain sulphur is what I cannot pretend to know, as I have not tried steel, or varieties enough of malleable iron. However, I have strong reason to suspect, that sulphur has more to do in the different properties of iron than we are aware of. That iron should contain sulphur, notwithstanding the different processes it must necessarily undergo before it acquires malleability, considering the volatility of sulphur, points out the force of their attraction to one another; and the separation of this again by volatile sulphureous acid, shows likewise the greater attraction of iron to sulphur and dephlogisticated air jointly. That volatile sulphureous acid should dissolve iron without the extrication of inflammable air or phlogiston, is a very strong instance of the fallacy of the phlogistic doctrine. A small quantity of inflammable air is produced, but it is so trifling comparatively to what should be produced from the quantity of iron dissolved, that it is hardly worth noticing; and in my

opinion proceeds from a portion of perfect vitriolic acid, which is generally inseparable from the volatile acid. If volatile vitriolic acid were a compound of phlogiston, a certain basis, and dephlogisticated air, a greater quantity of inflammable air should have been disengaged during the solution of iron in this acid than when the perfect vitriolic acid is used. Let us even suppose volatile sulphureous acid to be composed of the basis of sulphur, phlogiston, and dephlogisticated air, which is the opinion of all the Phlogistians, though they differ with respect to the modification of these three principles; and likewise iron to be composed of a certain basis and phlogiston; I would ask the Phlogistians, What becomes of the phlogiston of the iron during its solution?"

But however much Mr Higgins may be convinced, from this experiment, of the fallacy of the phlogistic doctrine, his adversaries, instead of being silenced, will urge his own experiment against himself. He owns, that during the solution something was separated of a black colour, and which burned like charcoal dust. Unless therefore Mr Higgins shall prove the contrary, they will say, that this was the real *phlogiston* or *charcoal* which entered into the substance of the metal; and that it appeared in its native form, because the volatile vitriolic acid had not specific or latent heat sufficient to convert it into inflammable air. At any rate, it was incumbent on Mr Higgins to have accounted for the coally part of his residuum as well as the sulphureous one; yet he has been at considerable pains to deduce the latter from the iron, without speaking a word about the former. Indeed, whether he deduced this from the iron or the vitriolic acid, it will make equally against him; for his principles do not allow that the volatile vitriolic acid contains any charcoal. That the latter really does so, however, appears from an experiment of Dr Priestley, in which he reduced a calx of lead by means of vitriolic acid air, the same with the vitriolic or volatile sulphureous acid. It is true, that only a small quantity of metal was thus procured; but however small this was, the Antiphlogistians do not pretend that metals can be reduced to their metallic state in any quantity, except by the mediation of charcoal.

Thus it appears, that with regard to metals the dispute is as yet far enough from being decided in favour of the Antiphlogistians. Their cause is equally doubtful with regard to sulphur and phosphorus, both of which Dr Priestley has produced by heating vitriolic and phosphoric acid in inflammable air. Indeed, by some experiments on sulphur, the matter seems to be decided against them. "Perhaps (says Dr Priestley) as decisive a proof as any, of the real production of fixed air from phlogiston and dephlogisticated air, may be drawn from the experiments in which I always found a quantity of it when I burned sulphur in dephlogisticated air. In one of these experiments to which I gave more particular attention, six ounce-measures and an half of the dephlogisticated air were reduced to about two ounce-measures, and one-fifth of this was fixed air." Now, though the Doctor inferred from this, that fixed air was composed of phlogiston and dephlogisticated air, on the supposition of sulphur containing phlogiston; yet, admitting from other proofs, that fixed air is composed of these two principles, the experiment

Charcoal.

Charcoal. riment unanswerably proves, that sulphur contains phlogiston or charcoal, though indeed in a very small quantity: but if the sulphur contained none at all, and the dephlogisticated air as little, as the Antiphlogistians would have it, how is it possible that a compound, of which phlogiston makes a part, should result from an union of the two *? Another experiment equally decisive, even with regard to metals, is that quoted from Dr Priestley in the place just referred to (A), where he obtained pure fixed air from a mixture of red precipitate and iron-filings. Now, according to the antiphlogistic doctrine, neither of these materials contained an atom of charcoal or phlogiston; whence then came the phlogiston in the fixed air which issued from the mixture?

Thus the Antiphlogistians seem to be unanswerably refuted with regard to sulphur and metallic substances; for if the two experiments just related be accurate, it is impossible to invalidate them by any argumentation whatever. Their last resource therefore is the decomposition of water: and even here it is evident they have little reason to boast. On this subject, however, we are sorry to observe, that the opinions have been so many, so various, and so fluctuating, that it is not only impossible to say what are the prevailing ones, but even difficult to ascertain what are the sentiments of any individual on the subject. Under the article AEROLOGY, n° 81. we have quoted Dr Priestley as favouring the doctrine of the decomposition of water; and in Mr Higgins's work we find him quoted

Comparative View, p. 3. as opposing it. "Dr Priestley (says he) supposes that the water produced by the condensation of inflammable and dephlogisticated air, is only what was suspended and attached to them in their elastic state, and that their respective gravitating particles form a different compound, namely, the nitrous acid. To ascertain this, he confined his mixture of airs with dry fixed alkali over mercury, in order to abstract from it as much water as possible. Having thus prepared his mixture of airs, he found, after exploding them, that the product of water fell far short of the weight of both airs; and he observed a dense vapour after every explosion, which soon condensed, and adhered in a solid state to the sides of the vessel, which he found afterwards to be the nitrous acid." To this Mr Higgins answers, that the airs ought to have been accurately weighed after abstracting the water from them, when (he supposes) the weight of water produced would have equalled them. This indeed ought to have been done; but Mr Higgins, or some Antiphlogistian, ought to have done so before he decided positively in favour of the opposite doctrine. At any rate, it cannot be pretended, that in any experiment, let the circumstances of it be what they would, the quantity of water produced ever equalled that of the two airs. It is evident therefore, that till this shall some how or other be cleared up, the matter must remain uncertain. That the purest water we can obtain always contains phlogiston, is what no Phlogistian denies; that it essentially belongs to it is doubtful, though indeed it must be

Charcoal. probable, that it does so until experiments show the contrary. Mr Cavendish supposes that *dephlogisticated* air and *dephlogisticated water* may be the same; and indeed this would seem to be almost certain, were it not for a circumstance taken notice of by Mr Higgins, viz. that in the firing of iron in dephlogisticated air the latter appears to be totally absorbed; though it is certain, that a quantity of undecomposed water enters into its composition.

How far this circumstance throws any obscurity on the matter the reader must determine. For a more full investigation of the subject, however, we must refer to the article WATER; and in the mean time shall dismiss the article with a few observations on the composition of charcoal.

From the days of Stahl till very lately, the component parts of this substance have been reckoned a certain kind of earth combined with what was called phlogiston. The late experiments of Dr Priestley have shown, that this doctrine is erroneous, and that charcoal is wholly dissippable into vapour. "On the whole (says the translator of Wiegley's Chemistry), charcoal appears, from the experiments of Lavoisier and Berthollet, to be an oil deprived of its inflammable gas. But coal of wood (or common charcoal) likewise contains fixed alkali, which the soot (or the coal of oil) does not, but instead of this exhibits volatile alkali. The fixed alkali of the former proceeds from the plant itself, and this, in the case of soot, is joined with inflammable gas, and forms volatile alkali, the earthy part being left behind, as happens when this latter is prepared from fixed alkali. Genuine charcoal, therefore, consists of this vegetable principle, united with a little fixed alkali and part of the phlogiston that constituted the oil of the plant of which it is made: for some of this principle is carried off, together with the *hydrophloge* (B), in the form of inflammable gas, if distilled in close vessels; but if burned in the open air, the hydrophloge unites with the pure part of the air, and forms water. From these considerations, as well as from the experiments and observations of M. Berthollet, in the Mem. de l'Acad. des Sciences pour 1786, p. 33. *et seq.* it appears, that common charcoal consists of the vegetable principle, some phlogiston, fixed alkali, and no inflammable gas."

On all this, however, we must observe, that it is entirely disproved by the experiments of Dr Priestley, so often quoted, in which it was totally dissipated into inflammable air *. On this occasion indeed he acknowledges, that some very minute particles of ashes were observed, which could not have amounted to a single grain from many pounds of wood. Even these, according to what he observes in the same place, may be supposed to have come from the small quantity of air in the receiver; and it is to be wished that the Doctor would repeat the experiment in one of those perfect vacuums through which the electric fluid cannot be made to pass. From undoubted experiments, however, it appears, that charcoal cannot be decomposed by mere heat; as in *vacuo* it is dissipated into inflammable air; and

* See *Aerology*, n° 129, 130.

(A) See *Encycl.* Vol. I. p. 169. col. 1. where, in lines 18, 19 from the top, read *precipitate* for *charcoal*.

(B) A word used by Mr Wiegley, as far as we can comprehend the author's meaning, for one of the component parts of water. See his *General System of Chemistry*, translated by Hopson, p. 39.

Charcoal. and this, on presenting a proper substance to attract the solid part, again discovers itself, by its blackness, to be real charcoal. As little does it appear destructible by burning in the open air; for though some ashes are left, it appears probable that these differ from the coal itself in nothing but having a quantity of air attached to them. By far the greatest part of it, even in the common way of burning, is converted into fixed air; and from this it may again be separated by taking the electric spark in that fluid, when it is resolved into very pure dephlogisticated and inflammable air. The same separation may be effected by merely heating iron in fixed air; in which case the dephlogisticated part will unite to the iron, and the coaly part, together with part of the phlogiston of the metal, be converted into inflammable air. From all these, and other considerations, a suspicion is induced, that the matter of charcoal is not different from the element of earth itself; and that, according to the different modifications of this substance, it either appears as coal, ashes, earth of various kinds, or even metals. This receives some confirmation from the following experiments of Mr Watt, related in the 74th volume of the Philosophical Transactions: "I dissolved (says he) magnesia alba, calcareous earth, and minium, in nitrous acid dephlogisticated by boiling, and diluted with proper proportions of water. I made use of glass-retorts coated with clay; and I received the air in glass-vessels, whose mouths were immersed in a glazed earthen basin containing the smallest quantity of water that could be used for the purpose. As soon as the retort was heated a little above the degree of boiling water, the solutions began to distil watery vapours containing nitrous acid. Soon after these vapours ceased, yellow fumes, and, in some of the cases, dark red fumes, began to appear in the neck of the retort; and, at the same time, there was a production of dephlogisticated air, which was greater in quantity from some of these mixtures than from others, but continued in all of them until the substances were reduced to dryness. I found in the receiving water, &c. very nearly the whole of the nitrous acid used for their solution, but highly phlogisticated, so as to emit nitrous air by the application of heat; and there is reason to believe, that with more precaution the whole might have been obtained. As the quantity of dephlogisticated air produced by these processes did not form a sufficient part of the whole weight to enable me to judge whether any of the real acid entered into the composition of the air I obtained, I ceased to pursue them further, having learned from them the fact, that however much the acid and the earths were dephlogisticated before the solution, the acid always became highly phlogisticated in the process."

"In order to examine whether this phlogiston was furnished by the earths, some dephlogisticated nitrous acid was distilled from minium till no more air or acid came over. More of the same acid was added to the minium as soon as it was cold, and the distillation repeated, which produced the same appearances of red fumes and dephlogisticated air. This operation was repeated a third time on the same minium, without any sensible variation in the phenomena. The process should have been still farther repeated, but the retort broke about the end of the third

distillation; the quantity of minium used was 120 grains, and the quantity of nitrous acid added each time was 240 grains, of such strength that it could dissolve half its weight of mercury by means of heat. It appears from this experiment, that unless minium be supposed principally to consist of phlogiston, the source of the phlogiston thus obtained, was either the nitrous acid itself, or the water with which it was diluted; or else that it came through the retort with the light; for the retort was in this case red hot before any air was produced. Yet this latter conclusion does not appear very satisfactory, when it is considered, that in the process wherein the earth made use of was magnesia, the retort was not red hot, or very obscurely so, in any part of the process, and by no means luminous when the yellow and red fumes first made their appearance."

To these experiments, however, the Antiphlogistians will no doubt reply, that there was no phlogiston in the case, and that the nitrous acid was only decomposed; and indeed the decisive experiment here would be, the entire dissipation of a quantity of earth into some kind of air, as may be done with charcoal; but to do this in the way of distillation must be attended with incredible labour, though, as finally deciding this point, it seems to be well worth pursuing.

A pretty strong proof of the identity of metallic calces with charcoal, is their conversion into it in the manner already related. Experiments, however, are yet wanting on the subject; though it seems probable from what Dr Priestley has already done, that they may thus be entirely dissipated into air as well as common charcoal.

CHARDIN (Sir John), a celebrated traveller, was born at Paris in 1643. His father, who was a jeweller, had him educated in the Protestant religion; after which he travelled into Persia and India. He traded in jewels, and died at London in 1713. The account he wrote of his travels is much esteemed.

CHARENTON, the name of two towns of France, the one upon the Marmaude in the Bourbonnois; the other in the isle of France, near the confluence of the Marne with the Seine.

CHARES the Lydian, a celebrated statuary, was the disciple of Lysippus; and made the famous Colossus of the sun in the city of Rhodes. Flourished 288 years before Christ.

CHARGE, in gunnery, the quantity of powder and ball wherewith a gun is loaded for execution.

The rules for charging large pieces in war are, That the piece be first cleaned or scoured within: that the proper quantity of powder be next driven in and rammed down; care, however, being taken, that the powder, in ramming, be not bruised, because that weakens its effect: that a little quantity of paper, hay, lint, or the like, be rammed over it; and that the ball or shot be intruded. If the ball be red-hot, a tompon, or trencher of green wood, is to be driven in before it. The common allowance for a charge of powder of a piece of ordnance, is half the weight of the ball. In the British Navy, the allowance for 32 pounders is but seven-sixteenths of the weight of the bullet. But a *Rollin's* *Pro-*late author is of opinion, that if the powder in all ship-*posul* for in- cannon whatever was reduced to one-third weight of *creasing the* the ball, or even less, it would be of considerable ad- *Strength of* vantage, not only by saving ammunition, but by keep- *the Navy.* ing

ing the guns cooler and quieter, and at the same time more effectually injuring the vessels of the enemy. With the present allowance of powder the guns are heated, and their tackle and furniture strained; and this only to render the bullets less efficacious: for a bullet which can but just pass through a piece of timber, and loses almost all its motion thereby, has a much better chance of rending and fracturing it, than if it passes through with a much greater velocity.

CHARGE, in heraldry, is applied to the figures represented on the escutcheon, by which the bearers are distinguished from one another; and it is to be observed, that too many charges are not so honourable as fewer.

CHARGE of Lead, denotes a quantity of 36 pigs. See FIG.

To CHARGE in the military language, is to attack the enemy either with horse or foot.

CHARGE, in law, denotes the instructions given to the grand jury, with respect to the articles of their inquiry, by the judge who presides on the bench.

CHARGE, in law, also signifies a thing done that bindeth him who doth it; and discharge is the removal of that charge. Lands may be charged in various ways; as, by grant of rent out of it, by statutes, judgments, conditions, warranties, &c.

CHARGE of horning, in Scots law. See HORNING.

CHARGE to enter Heir, in Scots law, a writing passing under the signet, obtained at the instance of a creditor, either against the heir of his debtor, for fixing upon him the debt as representing the debtor, which is called a general charge: or, against the debtor himself, or his heir, for the purpose of vesting him in the right of any heritable subject to which he has made up no title, in order the creditor may attach that subject for payment of his debt, in the same manner as if his debtor or his heir were legally vested in it by service or otherwise. This last kind is called a *special charge*.

CHARGE, or rather *Overcharge*, in painting, is an exaggerated representation of any person; wherein the likeness is preserved, but at the same time ridiculed.

Few painters have the genius necessary to succeed in these charges: the method is, to select and heighten something already amiss in the face, whether by way of defect, or redundancy: thus *v. g.* if Nature have given a man a nose a little larger than ordinary, the painter falls in with her, and makes the nose extravagantly long: or if the nose be naturally too short, in the painting it will be a mere stump; and thus of the other parts.

CHARGED, in heraldry, a shield carrying some impress or figure, is said to be charged therewith; so also, when one bearing, or charge, has another figure added upon it, it is properly said to be charged.

CHARGED, in electrical experiments, is when a vial, pane of glass, or other electric substance, properly coated on both sides, has a quantity of electricity communicated to it; in which case the one side is always electrified positively, and the other negatively.

CHARIOT, a half coach, having only a seat behind, with a stool before. See COACH.

The chariots of the ancients, chiefly used in war, were called by the several names *bige*, *trige*, &c. according to the number of horses applied to draw them.

Every chariot carried two men, who were probably the warrior and the charioteer; and we read of several men of note and valour employed in driving the chariot. When the warriors came to encounter in close fight, they alighted out of the chariot, and fought on foot; but when they were weary, which often happened by reason of their armour, they retired into their chariot, and thence annoyed their enemies with darts and missile weapons. These chariots were made so strong, that they lasted for several generations.

Besides this sort, we find frequent mention of the *currus falcati*, or those chariots armed with hooks, or scythes, with which whole ranks of soldiers were cut off together, if they had not the art of avoiding the danger; these were not only used by the Persians, Syrians, Egyptians, &c. but we find them among the ancient Britons; and notwithstanding the imperfect state of some of the most necessary arts among that nation before the invasion of the Romans, it is certain that they had war-chariots in great abundance. By the Greek and Roman historians, these chariots are described by the six following names; *viz.* Benna, Petoritum, Currus or Carrus, Covinus, Effedum, and Rheda. The benna seems to have been a chariot designed rather for travelling than war. It contained two persons, who were called *combennones*, from their sitting together in the same machine. The petoritum seems to have been a larger kind of chariot than the benna; and is thought to have derived its name from the British word *ped-war*, signifying *four*; this kind of carriage having four wheels. The carrus or currus was the common cart or waggon. This kind of chariot was used by the ancient Britons, in times of peace, for the purposes of agriculture and merchandise; and, in time of war, for carrying their baggage, and wives and children, who commonly followed the armies of all the Celtic nations. The covinus was a war-chariot, and a very terrible instrument of destruction; being armed with sharp scythes and hooks for cutting and tearing all who were so unhappy as to come within its reach. This kind of chariot was made very slight, and had few or no men in it besides the charioteer; being designed to drive with great force and rapidity, and to do execution chiefly with its hooks and scythes. The effedum and rheda were also war-chariots, probably of a large size, and stronger made than the covinus, designed for containing a charioteer for driving it, and one or two warriors for fighting. The far greatest number of the British war-chariots seem to have been of this kind. These chariots, as already observed, were to be found in great numbers among the Britons; insomuch that Cæsar relates that Cassibelanus, after dismissing all his other forces, retained no fewer than 4000 of these war-chariots about his person. The same author relates, that, by continual experience, they had at last arrived at such perfection in the management of their chariots, that "in the most steep and difficult places they could stop their horses upon full stretch, turn them which way they pleased, run along the pole, rest on the harness, and throw themselves back into their chariots, with incredible dexterity."

CHARIOTS, in the heathen mythology, were sometimes consecrated to the sun; and the scripture observes, that Josiah burnt those which had been offered to the sun by the king's predecessors. This superstitious

Chariot.

Chariot
||
Charity.

tious custom was an imitation of the heathens, and principally of the Persians, who had horses and chariots consecrated in honour of the sun. Herodotus, Xenophon, and Quintus Curtius, speak of white chariots crowned, which were consecrated to the sun, among the Persians, which in their ceremonies were drawn by white horses consecrated to the same luminary.

Triumphal CHARIOT, was one of the principal ornaments of the Roman celebration of a victory.

The Roman triumphal chariot was generally made of ivory, round like a tower, or rather of a cylindrical figure; it was sometimes gilt at the top, and ornamented with crowns; and to represent a victory more naturally, they used to stain it with blood. It was usually drawn by four white horses; but oftentimes by lions, elephants, tygers, bears, leopards, dogs, &c.

CHARISIA, in the heathen theology, a wake, or night-festival, instituted in honour of the graces. It continued the whole night, most of which time was spent in dancing; after which, cakes made of yellow flour mixed with honey, and other sweetmeats, were distributed among the assistants.—*Charisia* is also sometimes used to signify the sweetmeats used on such occasions.

CHARISIUS, in the heathen theology, a surname given to Jupiter. The word is derived from *χαρις*, *gratia*, “grace” or “favour;” he being the God by whose influence men obtain the favour and affection of one another. On which account the Greeks used at their meals to make a libation of a cup to Jupiter *Charisius*.

CHARISTIA, a festival of the ancient Romans, celebrated in the month of February, wherein the relations by blood and marriage met, in order to preserve a good correspondence; and that if there happened to be any difference among them, it might be the more easily accommodated, by the good humour and mirth of the entertainment. *Ovid. Fast. i. 617.*

CHARISTICARY, commendatory, or donatory, a person to whom is given the enjoyment of the revenues of a monastery, hospital, or benefice.

The *charisticaries* among the Greeks, were a kind of donatories, or commendatories, who enjoyed all the revenues of hospitals and monasteries, without giving an account thereof to any person.—The original of this abuse is referred to the Iconoclastæ, particularly Constantine Copronymus, the avowed enemy of the monks, whose monasteries he gave away to strangers. In after times, the emperors and patriarchs gave many to people of quality, not by way of gift, to reap any temporal advantage from them; but to repair, beautify, and patronize them. At length avarice crept in, and those in good condition were given away, especially such as were rich; and at last they were all given away, rich and poor, those of men and of women, and that to laymen and married men.

CHARITY, among divines, one of the three grand theological virtues, consisting in the love of God and of our neighbour, or the habit and disposition of loving God with all our heart, and our neighbour as ourselves.

CHARITY is also used for the effect of a moral virtue, which consists in supplying the necessities of others, whether with money, counsel, assistance, or the like.

Charity.

As pecuniary relief is generally the most efficacious, and at the same time that from which we are most apt to excuse ourselves, this branch of the duty merits particular illustration; and a better cannot be offered than what is contained in the following extracts (if we may be permitted to make them) from the elegant *Moral System* of Archdeacon Paley.

Whether pity be an instinct or a habit, it is in fact a property of our nature, which God appointed: and the final cause for which it was appointed, is to afford to the miserable, in the compassion of their fellow-creatures, a remedy for those inequalities and distresses which God foresaw that many must be exposed to, under every general rule for the distribution of property.

The Christian scriptures are more copious and explicit upon this duty than almost any other. The description which Christ hath left us of the proceedings of the last day, establishes the obligation of bounty beyond controversy. “When the Son of man shall come in his glory, and all the holy angels with him, then shall he sit upon the throne of his glory, and before him shall be gathered all nations; and he shall separate them one from another. Then shall the king say unto them on his right hand, Come ye blessed of my father, inherit the kingdom prepared for you from the foundation of the world: For I was an hungered, and ye gave me meat; I was thirsty, and ye gave me drink; I was a stranger, and ye took me in; naked, and ye clothed me; I was sick, and ye visited me; I was in prison, and ye came unto me. And inasmuch as ye have done it to one of the least of these my brethren, ye have done it unto me.” It is not necessary to understand this passage as a literal account of what will actually pass on that day. Supposing it only a scenical description of the rules and principles by which the Supreme Arbiter of our destiny will regulate his decisions, it conveys the same lesson to us; it equally demonstrates of how great value and importance these duties in the sight of God are, and what stress will be laid upon them. The apostles also describe this virtue as propitiating the divine favour in an eminent degree. And these recommendations have produced their effect. It does not appear that, before the times of Christianity, an infirmary, hospital, or public charity of any kind, existed in the world; whereas most countries in Christendom have long abounded with these institutions. To which may be added, that a spirit of private liberality seems to flourish amidst the decay of many other virtues: not to mention the legal provision for the poor, which obtains in this country, and which was unknown and unthought of by the most polished nations of antiquity.

St Paul adds upon the subject an excellent direction; and which is practicable by all who have any thing to give. “Upon the first day of the week (or any other stated time) let every one of you lay by in store, as God hath prospered him.” By which the apostle may be understood to recommend what is the very thing wanting with most men, *the being charitable upon a plan*; that is, from a deliberate comparison of our fortunes with the reasonable expences and expectations of our families, to compute what we can spare, and to lay by so much for charitable purposes, in some mode or other. The mode will be a consideration afterwards.

The

Charity.

The effect, which Christianity produced upon some of its converts, was such as might be looked for from a divine religion coming with full force and miraculous evidence upon the consciences of mankind. It overwhelmed all worldly considerations in the expectation of a more important existence. "And the multitude of them that believed were of one heart and of one soul; neither said any of them that aught of the things, which he possessed, was his own; but they had all things in common.—Neither was there any among them that lacked; for as many as were possessors of lands or houses sold them, and brought the prices of the things that were sold, and laid them down at the apostles' feet; and distribution was made unto every man, according as he had need." Acts iv. 32.

Nevertheless, this community of goods, however it manifested the sincere zeal of the primitive Christians, is no precedent for our imitation. It was confined to the church at Jerusalem; continued not long there; was never enjoined upon any (Acts v. 4.); and, although it might suit with the particular circumstances of a small and select society, is altogether impracticable in a large and mixed community.

The conduct of the apostles upon the occasion deserves to be noticed. Their followers laid down their fortunes at their feet: but so far were they from taking advantage of this unlimited confidence to enrich themselves or establish their authority, that they soon after got rid of this business as inconsistent with the main object of their mission, and transferred the custody and management of the public fund to deacons, elected to that office by the people at large. (Acts vi.)

There are three kinds of charity, our author observes, which prefer a claim to attention.

1. The first, and apparently one of the best, is to give stated and considerable sums, by way of pension or annuity to individuals or families, with whose behaviour and distress we ourselves are acquainted. In speaking of considerable sums, it is meant only, that five pounds, or any other sum, given at once, or divided amongst five or fewer families, will do more good than the same sum distributed amongst a greater number in shillings or half crowns; and that, because it is more likely to be properly applied by the persons who receive it. A poor fellow, who can find no better use for a shilling than to drink his benefactor's health, and purchase half an hour's recreation for himself, would hardly break into a guinea for any such purpose, or be so improvident as not to lay it by for an occasion of importance, for his rent, his clothing, fuel, or stock of winter's provision. It is a still greater recommendation of this kind of charity, that pensions and annuities, which are paid regularly, and can be expected at the time, are the only way by which we can prevent one part of a poor man's sufferings, the dread of want.

2. But as this kind of charity supposes that proper objects of such expensive benefactions fall within our private knowledge and observation, which does not happen to all, a second method of doing good, which is in every one's power who has the money to spare, is by subscription to public charities. Public charities admit of this argument in their favour, that your money goes farther towards attaining the end for which it is given, than it can do by any private and separate

beneficence. A guinea, for example, contributed to an infirmary, becomes the means of providing one patient, at least, with a physician, surgeon, apothecary; with medicine, diet, lodging, and suitable attendance; which is not the tenth part of what the same assistance, if it could be procured at all, would cost to a sick person or family in any other situation.

3. The last, and, compared with the former, the lowest exertion of benevolence, is in the relief of beggars. Nevertheless, the indiscriminate rejection of all who implore our alms in this way, is by no means approved. Some may perish by such a conduct. Men are sometimes overtaken by distress, for which all other relief would come too late. Besides which, resolutions of this kind compel us to offer such violence to our humanity, as may go near, in a little while, to suffocate the principle itself; which is a very serious consideration. A good man, if he do not surrender himself to his feelings without reserve, will at least lend an ear to importunities which come accompanied with outward attestations of distress; and after a patient hearing of the complaint, will direct himself by the circumstances and credibility of the account that he receives.

There are other species of charity well contrived to make the money expended *go far*; such as keeping down the price of fuel or provision in case of a monopoly or temporary scarcity, by purchasing the articles at the best market, and retailing them at prime cost, or at a small loss; or the adding a bounty to a particular species of labour, when the price is accidentally depressed.

The proprietors of large estates have it in their power to facilitate the maintenance, and thereby encourage the establishment of families (which is one of the noblest purposes to which the rich and great can convert their endeavours), by building cottages, splitting farms, erecting manufactures, cultivating wastes, embanking the sea, draining marshes, and other expedients, which the situation of each estate points out. If the profits of these undertakings do not repay the expence, let the authors of them place the difference to the account of charity. It is true of almost all such projects, that the public is a gainer by them, whatever the owner be. And where the loss can be spared, this consideration is sufficient.

It is become a question of some importance, Under what circumstances works of charity ought to be done in private, and when they may be made public without detracting from the merit of the action; if indeed they ever may, the Author of our religion having delivered a rule upon this subject, which seems to enjoin universal secrecy. "When thou doest alms, let not thy left hand know what thy right hand doth; that thy alms may be in secret, and thy Father which seeth in secret, himself shall reward thee openly." (Matth. vi. 3, 4.) From the preamble to this prohibition, it is plain, that our Saviour's sole design was to forbid ostentation, and all publishing of good works which proceeds from that motive. "Take heed that ye do not your alms before men, to be seen of them; otherwise ye have no reward of your Father, which is in heaven: therefore, when thou doest thine alms, do not sound a trumpet before thee, as the hypocrites do, in the synagogues and in the streets, that they may have glory of men."

Charity.

Charity. *men.* Verily I say unto thee, they have their reward," v. 2. There are motives for the doing our alms in public beside those of ostentation; with which therefore our Saviour's rule has no concern: such as to testify our approbation of some particular species of charity, and to recommend it to others; to take off the prejudice which the want, or, which is the same thing, the suppression, of our name in the list of contributors, might excite against the charity or against ourselves. And, so long as these motives are free from any mixture of vanity, they are in no danger of invading our Saviour's prohibition: they rather seem to comply with another direction which he has left us: "Let your light so shine before men, that they may see your good works, and glorify your father which is in heaven." If it be necessary to propose a precise distinction upon the subject, there can be none better than the following: When our bounty is beyond our fortune or station, that is, when it is more than could be expected from us, our charity should be private, if privacy be practicable; when it is not more than might be expected, it may be public: for we cannot hope to influence others to the imitation of extraordinary generosity, and therefore want, in the former case, the only justifiable reason for making it public.

The pretences by which men excuse themselves from giving to the poor, are various; as,

1. "That they have nothing to spare;" i. e. nothing, for which they have not some other use; nothing, which their plan of expence, together with the savings they have resolved to lay by, will not exhaust: never reflecting whether it be in their power, or that it is their duty, to retrench their expences, and contract their plan, "that they may have to give to them that need;" or rather that this ought to have been part of their plan originally.

2. "That they have families of their own, and that charity begins at home." A father is no doubt bound to adjust his œconomy with a view to the reasonable demands of his family upon his fortune; and until a sufficiency for these is acquired, or in due time probably will be acquired (for in human affairs probability is enough), he is justified in declining *expensive* liberality; for to take from those who want, in order to give to those who want, adds nothing to the stock of public happiness. Thus far, therefore, and no farther, the plea in question is an excuse for parsimony, and an answer to those who solicit our bounty.

3. "That charity does not consist in giving money, but in benevolence, philanthropy, love to all mankind, goodness of heart," &c. Hear St James. "If a brother or sister be naked, and destitute of daily food, and one of you say unto them, depart in peace, be ye warmed and filled, notwithstanding ye give them not those things which are needful to the body, what doth it profit?" (James ii. 15, 16.)

4. "That giving to the poor is not mentioned in St Paul's description of charity, in the 13th chapter of his first epistle to the Corinthians." This is not a description of charity, but of good nature; and it is not necessary that every duty be mentioned in every place.

5. "That they pay the poor-rates." They might as well allege that they pay their debts; for the poor

have the same right to that portion of a man's property, which the laws assign them, that the man himself has to the remainder.

6. "That they employ many poor persons:"—for their own sake, not the poor's—otherwise it is a good plea.

7. "That the poor do not suffer so much as we imagine; that education and habit have reconciled them to the evils of their condition, and make them easy under it." Habit can never reconcile human nature to the extremities of cold, hunger, and thirst, any more than it can reconcile the hand to the touch of a red-hot iron: besides, the question is not, how unhappy any one is, but how much more happy we can make him.

8. "That these people, give them what you will, will never thank you, or think of you for it." In the first place, this is not true: in the second place, it was not for the sake of their thanks that you relieved them.

9. "That we are so liable to be imposed upon." If a due enquiry be made, our motive and merit is the same: beside that, the distress is generally real, whatever has been the cause of it.

10. "That they should apply to their parishes." This is not always practicable: to which we may add, that there are many requisites to a comfortable subsistence, which parish-relief does not always supply; and that there are some who would suffer almost as much from receiving parish-relief as by the want of it: and lastly, that there are many modes of charity, to which this answer does not relate at all.

11. "That giving money encourages idleness and vagrancy." This is true only of injudicious and indiscriminate generosity.

12. "That we have too many objects of charity at home to bestow any thing upon strangers; or that there are other charities which are more useful, or stand in greater need." The value of this excuse depends entirely upon the *fact*, whether we actually relieve those neighbouring objects, and contribute to those other charities.

Beside all these excuses, pride, or prudery, or delicacy, or love of ease, keep one half of the world out of the way of observing what the other half suffer.

CHARITY Schools, are schools erected and maintained in various parishes by the voluntary contributions of the inhabitants, for teaching poor children to read, write, and other necessary parts of education. See *SCHOOL*.

Brothers of CHARITY, a sort of religious hospitallers, founded about the year 1297, since denominated *Billets*. They took the third order of St Francis, and the scapulary, making three usual vows, but without begging.

Brothers of CHARITY also denote an order of hospitallers still subsisting in Romish countries, whose business is to attend the sick poor, and minister to them both spiritual and temporal succour.

They are all laymen, except a few priests, for administering the sacraments to the sick in their hospitals. The brothers of charity usually cultivate botany, pharmacy, surgery, and chemistry, which they practise with success.

They were first founded at Granada, by St John de Dieu;

Charity
||
Charle-
mont.

Dieu; and a second establishment was made at Madrid in the year 1553: the order was confirmed by Gregory XIII. in 1572: Gregory XIV. forbade them to take holy orders; but by leave of Paul V. in 1609, a few of the brothers might be admitted to orders. In 1619 they were exempted from the jurisdiction of the bishop. Those of Spain are separated from the rest; and they, as well as the brothers of France, Germany, Poland, and Italy, have their distinct generals, who reside at Rome. They were first introduced into France by Mary of Medicis in 1601, and have since built a fine hospital in the Faubourg St Germain.

CHARITY of St Hippolitus, a religious congregation founded about the end of the 14th century, by one Bernardin Alvarez, a Mexican, in honour of St Hippolitus the martyr, patron of the city of Mexico; and approved by Pope Gregory XIII.

CHARITY of our Lady, in church-history, a religious order in France, which, though charity was the principal motive of their union, grew in length of time so disorderly and irregular, that their order dwindled, and at last became extinct.

There is still at Paris a religious order of women, called *nuns hospitallers of the charity of our lady*. The religious of this hospital are by vow obliged to administer to the necessities of the poor and the sick, but those only women.

CHARLATAN, or CHARLETAN, signifies an empiric or quack, who retails his medicines on a public stage, and draws people about him with his buffooneries, feats of activity, &c. The word, according to Calepine, comes from the Italian *ceretano*; of *Ceretum*, a town near Spoleto in Italy, where these impostors are said to have first risen. Menage derives it from *ciarlatano*, and that from *circulatorius*, of *circulator*, a quack.

CHARLEMAGNE, or Charles I. king of France by succession, and emperor of the west by conquest in 800, (which laid the foundation of the dynasty of the western Franks, who ruled the empire 472 years till the time of Radolphus Auspurgensis, the founder of the house of Austria). Charlemagne was as illustrious in the cabinet as in the field; and, though he could not write his name, was the patron of men of letters, the restorer of learning, and a wise legislator: he wanted only the virtue of humanity to render him the most accomplished of men; but when we read of his beheading 4500 Saxons, solely for their loyalty to their prince, in opposing his conquests, we cannot think he merits the extravagant encomiums bestowed on him by some historians. He died in 814, in the 74th year of his age, and 47th of his reign.

France had nine sovereigns of this name, of whom Charles V. merited the title of *the wise*, (crowned in 1364, died in 1380): and Charles VIII. signalized himself in the field by rapid victories in Italy; crowned 1483, died in 1498. The rest do not deserve particular mention in this place. See (*History of*) FRANCE.

CHARLEMONT, a town of the province of Namur in the Austrian Netherlands, about 18 miles south of Namur. E. Long. 4. 40. N. Lat. 50. 10.

CHARLEMONT is also the name of a town of Ireland, situated on the river Blackwater, in the county

of Armagh, and province of Ulster, about six miles south-east of Dungannon. W. Long. 6. 50. N. Lat. 50. 16.

Charleroy,
Charles.

CHARLEROY, a strong town in the province of Namur, in the Austrian Netherlands, situated on the river Sambre, about 19 miles west of Namur. E. Long. 4. 20. N. Lat. 50. 30.

CHARLES MARTEL, a renowned conqueror in the early annals of France. He deposed and restored Chilperic king of France; and had the entire government of the kingdom, once with the title of *mayor of the palace*, and afterwards as *duke of France*; but he would not accept the crown. He died, regretted, in 741.

CHARLES le Gros, emperor of the west in 881, king of Italy and Suabia, memorable for his reverse of fortune; being dethroned at a diet held near Mentz, by the French, the Italians, and the Germans, in 887: after which he was obliged to subsist on the bounty of the archbishop of Mentz. He died in 888.

CHARLES V. (emperor and king of Spain), was son of Philip I. archduke of Austria, and of Jane queen of Castile. He was born at Ghent, February 24. 1500, and succeeded to the crown of Spain in 1517. Two years afterwards he was chosen emperor at Francfort after the death of Maximilian his grandfather. He was a great warrior and politician: and his ambition was not satisfied with the many kingdoms and provinces he possessed; for he is supposed, with reason, to have aspired at universal empire. He is said to have fought 60 battles, in most of which he was victorious. He took the king of France (Francis I.) prisoner, and sold him his liberty on very hard terms: yet afterwards, when the people of Ghent revolted, he asked leave to pass through his dominions; and though the generous king thus had him in his power, and had an opportunity of revenging his ill-treatment, yet he received and attended him with all pomp and magnificence. He sacked Rome, and took the Pope prisoner; and the cruelties which his army exercised there are said to have exceeded those of the northern barbarians. Yet the pious emperor went into mourning on account of this conquest: forbade the ringing of bells; commanded processions to be made, and prayers to be offered up for the deliverance of the Pope his prisoner; yet did not inflict the least punishment on those who treated the holy father and the holy see with such inhumanity. He is accused by some Romish writers of favouring the Lutheran principles, which he might easily have extirpated. But the truth is, he found his account in the divisions which that sect occasioned; and he for ever made his advantage of them, sometimes against the Pope, sometimes against France, and at other times against the empire itself. He was a great traveller, and made 50 different journeys into Germany, Spain, Italy, Flanders, France, England, and Africa. Though he had been successful in many unjust enterprizes, yet his last attempt on Metz, which he besieged with an army of 100,000 men, was very just and very unsuccessful.

Vexed at the reverse of fortune which seemed to attend his latter days, and oppressed by sickness, which unfitted him any longer from holding the reins of government with steadiness, or to guide them with address,

Charles.

dress, he resigned his dominions to his brother Ferdinand and his son Philip; and retreated to the monastery of St Justus near Placentia in Estramadura.

When Charles entered this retreat, he formed such a plan of life for himself as would have suited a private gentleman of moderate fortune. His table was neat, but plain; his domestics few; his intercourse with them familiar; all the cumbersome and ceremonious forms of attendance on his person were entirely abolished, as destructive of that social ease and tranquillity which he courted in order to sooth the remainder of his days. As the mildness of the climate, together with his deliverance from the burdens and cares of government, procured him at first a considerable remission from the acute pains of the gout, with which he had been long tormented, he enjoyed perhaps more complete satisfaction in this humble solitude than all his grandeur had ever yielded him. The ambitious thoughts and projects which had so long engrossed and disquieted him, were quite effaced from his mind. Far from taking any part in the political transactions of the princes of Europe, he restrained his curiosity even from an inquiry concerning them; and he seemed to view the busy scene which he had abandoned with all the contempt and indifference arising from his thorough experience of its vanity, as well as from the pleasing reflection of having disentangled himself from its cares.

Other amusements, and other objects, now occupied him. Sometimes he cultivated the plants in his garden with his own hand; sometimes he rode out to the neighbouring wood on a little horse, the only one that he kept, attended by a single servant on foot. When his infirmities confined him to his apartment, which often happened, and deprived him of these more active recreations, he either admitted a few gentlemen who resided near the monastery to visit him, and entertained them familiarly at his table; or he employed himself in studying mechanical principles, and in forming curious works of mechanism, of which he had always been remarkably fond, and to which his genius was peculiarly turned. With this view he had engaged Turriano, one of the most ingenious artists of that age, to accompany him in his retreat. He laboured together with him in framing models of the most useful machines, as well as in making experiments with regard to their respective powers; and it was not seldom that the ideas of the monarch assisted or perfected the inventions of the artist. He relieved his mind at intervals with slighter and more fantastic works of mechanism, in fashioning puppets, which, by the structure of internal springs, mimicked the gestures and actions of men, to the no small astonishment of the ignorant monks, who, beholding movements which they could not comprehend, sometimes distrusted their own senses, and sometimes suspected Charles and Turriano of being in compact with invisible powers. He was particularly curious with regard to the construction of clocks and watches; and having found, after repeated trials, that he could not bring any two of them to go exactly alike, he reflected, it is said, with a mixture of surprise as well as regret on his own folly, in having bestowed so much time and labour in the more vain attempt of bringing mankind to a precise uniformity of

sentiment concerning the intricate and mysterious doctrines of religion.

But in what manner soever Charles disposed of the rest of his time, he constantly reserved a considerable portion of it for religious exercises. He regularly attended divine service in the chapel of the monastery every morning and evening; he took great pleasure in reading books of devotion, particularly the works of St Augustine and St Bernard; and conversed much with his confessor, and the prior of the monastery, on pious subjects. Thus did Charles pass the first year of his retreat in a manner not unbecoming a man perfectly disengaged from the affairs of this present life, and standing on the confines of a future world, either in innocent amusements which soothed his pains, and relieved a mind worn out with excessive application to business; or in devout occupations, which he deemed necessary in preparing for another state.

But, about six months before his death, the gout, after a longer intermission than usual, returned with a proportional increase of violence. His shattered constitution had not strength enough remaining to withstand such a shock. It enfeebled his mind as much as his body; and from this period we hardly discern any traces of that sound and masculine understanding which distinguished Charles among his contemporaries. An illiberal and timid superstition depressed his spirit. He had no relish for amusements of any kind. He endeavoured to conform, in his manner of living, to all the rigour of monastic austerity. He desired no other society than that of monks, and was almost continually employed in chanting with them the hymns of the missal. As an expiation for his sins, he gave himself the discipline in secret with such severity, that the whip of cords which he employed as the instrument of his punishment, was found, after his decease, tinged with his blood. Nor was he satisfied with these acts of mortification, which, however severe, were not unexampled. The timorous and distrustful solicitude which always accompanies superstition, still continued to disquiet him, and depreciating all that he had done, prompted him to aim at something extraordinary, at some new and singular act of piety, that would display his zeal, and merit the favour of heaven. The act on which he fixed was as wild and uncommon as any that superstition ever suggested to a disordered fancy. He resolved to celebrate his own obsequies before his death. He ordered his tomb to be erected in the chapel of the monastery. His domestics marched thither in funeral procession, with black tapers in their hands. He himself followed in his shroud. He was laid in his coffin with much solemnity. The service for the dead was chanted; and Charles joined in the prayers which were offered up for the rest of his soul, mingled his tears with those which his attendants shed, as if they had been celebrating a real funeral. The ceremony closed with sprinkling holy water on the coffin in the usual form, and, all the assistants retiring, the doors of the chapel were shut. Then Charles rose out of the coffin, and withdrew to his apartment, full of those awful sentiments which such a singular solemnity was calculated to inspire. But either the fatiguing length of the ceremony,

Charles.

Charles. remony, or the impresson which this image of death left on his mind, affected him so much, that next day he was seized with a fever. His feeble frame could not long resist its violence; and he expired on the 21st of September, after a life of 58 years six months and 21 days.

CHARLES I. } Kings of Britain. See BRITAIN,

CHARLES II. } n^o 49, — 254.

CHARLES XII. king of Sweden, was born in 1682. By his father's will, the administration was lodged in the hands of the queen-dowager Eleonora with five senators, till the young prince was 18: but he was declared major at 15, by the states convened at Stockholm. The beginning of his administration raised no favourable ideas of him, as he was thought both by Swedes and foreigners to be a person of mean capacity. But the difficulties that gathered round him, soon afforded him an opportunity to display his real character. Three powerful princes, Frederic king of Denmark, Augustus king of Poland and elector of Saxony, and Peter the Great czar of Muscovy, presuming on his youth, conspired his ruin almost at the same instant. Their measures alarming the council, they were for diverting the storm by negotiations; but Charles, with a grave resolution that astonished them, said, "I am resolved never to enter upon an unjust war, nor to put an end to a just one but by the destruction of my enemies. My resolution is fixed: I will attack the first who shall declare against me; and when I have conquered him, I may hope to strike a terror into the rest." The old counsellors received his orders with admiration; and were still more surprised when they saw him on a sudden renounce all the enjoyments of a court, reduce his table to the utmost frugality, dress like a common soldier, and, full of the ideas of Alexander and Cæsar, propose those two conquerors for his models in every thing but their vices. The king of Denmark began by ravaging the territories of the duke of Holstein. Upon this Charles carried the war into the heart of Denmark; and made such a progress, that the king of Denmark thought it best to accept of peace, which was concluded in 1700. He next resolved to advance against the king of Poland, who had blocked up Riga. He had no sooner given orders for his troops to go into winter-quarters, than he received advice that Narva, where count Horne was governor, was besieged by an army of 100,000 Muscovites. This made him alter his measures, and move toward the Czar; and at Narva he gained a surprising victory, which cost him not above 2000 men killed and wounded. The Muscovites were forced to retire from the provinces they had invaded. He pursued his conquests, till he penetrated as far as where the diet of Poland was sitting; when he made them declare the throne of Poland vacant, and elect Stanislaus their king: then making himself master of Saxony, he obliged Augustus himself to renounce the crown of Poland, and acknowledge Stanislaus by a letter of congratulation on his accession. All Europe was surprised with the expeditious finishing of this great negotiation, but more at the disinterestedness of the king of Sweden, who satisfied himself with the bare reputation of this victory, without demanding an inch of

ground for enlarging his dominions. After thus reducing the king of Denmark to peace, placing a new king on the throne of Poland, having humbled the emperor of Germany, and protected the Lutheran religion, Charles prepared to penetrate into Muscovy in order to dethrone the Czar. He quickly obliged the Muscovites to abandon Poland, pursued them into their own country, and won several battles over them. The Czar, disposed to peace, ventured to make some proposals; Charles only answered, "I will treat with the Czar at Moscow." When this haughty answer was brought to Peter, he said, "My brother Charles still affects to act the Alexander, but I flatter myself he will not in me find a Darius." The event justified him: for the Muscovites, already beaten into discipline, and under a prince of such talents as Peter, entirely destroyed the Swedish army at the memorable battle of Pultowa, July 8. 1709; on which decisive day, Charles lost the fruits of nine years labour, and of almost 100 battles! The king, with a small troop, pursued by the Muscovites, passed the Boristhenes to Oczakow in the Turkish territories: and from thence, through desert countries, arrived at Bender; where the Sultan, when informed of his arrival, sent orders for accommodating him in the best manner, and appointed him a guard. Near Bender Charles built a house, and intrenched himself; and had with him 1800 men, who were all clothed and fed, with their horses, at the expence of the Grand Signior. Here he formed a design of turning the Ottoman arms upon his enemies; and is said to have had a promise from the Vizir of being sent into Muscovy with 200,000 men. While he remained here, he insensibly acquired a taste for books: he read the tragedies of Corneille and Racine, with the works of Despreaux, whose satires he relished, but did not much admire his other works. When he read that passage in which the author represents Alexander as a fool and a madman, he tore out the leaf. He would sometimes play at chess: but when he recovered of his wounds, he renewed his fatigues in exercising his men; he tired three horses a day; and those who courted his favour were all day in their boots. To dispose the Ottoman Porte to this war, he detached about 800 Poles and Cosaques of his retinue, with orders to pass the Neister, that runs by Bender, and to observe what passed on the frontiers of Poland. The Muscovite troops, dispersed in those quarters, fell immediately upon this little company, and pursued them even to the territories of the Grand Signior. This was what the king expected. His ministers at the Porte excited the Turks to vengeance; but the Czar's money removed all difficulties, and Charles found himself in a manner prisoner among the Tartars. He imagined the Sultan was ignorant of the intrigues of his Grand Vizir. Poniatosky undertook to make his complaints to the Grand Signior. The sultan, in answer, some days after, sent Charles five Arabian horses, one of which was covered with a saddle and housings of great riches; with an obliging letter, but conceived in such general terms, as gave reason to suspect that the minister had done nothing without the sultan's consent: Charles therefore refused them. Poniatosky had the courage to form a design of deposing the Grand Vizir; who

Charles.

Charles, who accordingly was deprived of his dignity and wealth, and banished. The seal of the empire was given to Numan Cuproughly: who persuaded his master, that the law forbid him to invade the Czar, who had done him no injury; but to succour the king of Sweden as an unfortunate prince in his dominions. He sent his majesty 800 purses, every one of which amounted to 500 crowns, and advised him to return peaceably to his own dominions. Charles rejected this advice, threatening to hang up the bashaws, and shave the beards of any Janisaries who brought him such messages; and sent word that he should depend upon the Grand Signior's promise, and hoped to re-enter Poland as a conqueror with an army of Turks. After various intrigues at the Porte, an order was sent to attack this *head of iron*, as he was called, and to take him either alive or dead. He stood a siege in his house, with forty domestics, against the Turkish army; killed no less than 20 Janisaries with his own hand; and performed prodigies of valour on a very unnecessary and unwarrantable occasion. But the house being set on fire, and himself wounded, he was at last taken prisoner, and sent to Adrianople; where the Grand Signior gave him audience, and promised to make good all the damages he had sustained. At last, after a stay of above five years, he left Turkey; and, having disguised himself, traversed Wallachia, Transylvania, Hungary, and Germany, attended only by one person: and in 16 days riding, during which time he never went to bed, came to Stralsund at midnight, November 21. 1714. His boots were cut from his swollen legs, and he was put to bed; where when he had slept some hours, the first thing he did was to review his troops, and examine the state of the fortifications. He sent out orders that very day, to renew the war with more vigour than ever. But affairs were now much changed: Augustus had recovered the throne of Poland; Sweden had lost many of its provinces, and was without money, trade, credit, or troops. The kings of Denmark and Prussia seized the island of Rugen; and besieged him in Stralsund, which surrendered; but Charles escaped to Carelsroon. When his country was threatened with invasion by so many princes, he, to the surprise of all Europe, marched into Norway with 20,000 men. A very few Danes might have stopped the Swedish army; but such a quick invasion they could not foresee. Europe was yet more at a loss to find the Czar so quiet, and not making a descent upon Sweden, as he had before agreed with his allies. This inaction was the consequence of one of the greatest designs, and at the same time the most difficult of any that were ever formed by the imagination of man. In short, a scheme was set on foot for a reconciliation with the Czar; for replacing Stanislaus on the throne of Poland; and setting James the second's son upon that of England, beside restoring the duke of Holstein to his dominions. Charles was pleased with these grand ideas, though without building much upon them, and gave his minister leave to act at large. In the mean time, Charles was going to make a second attempt upon Norway in 1718; and he flattered himself with being master of that kingdom in six months: but while he was examining the works at Fredericshall, a place of great

strength and importance, which is reckoned to be the key of that kingdom, he was killed by a shot from the enemy, as has been generally believed; though it has been also reported that he fell by the treachery of one of his own officers, who had been bribed for that purpose.

This prince experienced the extremes of prosperity and of adversity, without being softened by the one, or disturbed for a moment at the other; but was a man rather extraordinary than great, and fitter to be admired than imitated. He was honoured by the Turks for his rigid abstinence from wine, and his regularity in attending public devotion.

As to his person, he was tall and of a noble mien, had a fine open forehead, large blue eyes, flaxen hair, fair complexion, an handsome nose, but little beard, and a laugh not agreeable. His manners were harsh and austere, not to say savage: and as to religion, he was indifferent towards all, though exteriorly a Lutheran, and a strong believer in predestination. A few anecdotes will illustrate his character. No dangers, however great, made the least impression upon him. When a horse or two were killed under him at the battle of Narva in 1700, he leaped nimbly upon fresh ones, saying, "these people find me exercise." One day, when he was dictating letters to a secretary, a bomb fell through the roof into the next room of the house, where they were sitting. The secretary, terrified lest the house should come down upon them, let his pen drop out of his hand: "What is the matter," says the king calmly. The secretary could only reply, "Ah, Sir, the bomb." "The bomb (says the king)! what has the bomb to do with what I am dictating to you? Go on."

He preserved more humanity than is usually found among conquerors. Once, in the middle of an action, finding a young Swedish officer wounded and unable to march, he obliged the officer to take his horse, and continued to command his infantry on foot. The princess Lubomirski, who was very much in the interest and good graces of Augustus, falling by accident into the hands of one of his officers, he ordered her to be set at liberty; saying, "that he did not make war with women." One day, near Leipzig, a peasant threw himself at his feet, with a complaint against a grenadier, that he had robbed him of certain eatables provided for himself and his family. "Is it true (said Charles sternly), that you have robbed this man?" The soldier replied, "Sir, I have not done near so much harm to this man as your majesty has done to his master; for you have taken from Augustus a kingdom, whereas I have only taken from this poor scoundrel a dinner." Charles made the peasant amends, and pardoned the soldier for his firmness: "However, my friend (says he to him), you will do well to recollect, that if I took a kingdom from Augustus, I did not take it for myself."

Though Charles lived hardily himself, a soldier did not fear to remonstrate to him against some bread, which was very black and mouldy, and which yet was the only provision the troops had. Charles called for a piece of it, and calmly eat it up; saying, "that it was indeed not good, but that it might be eaten." From the danger he was in in Poland, when he beat

Charles.

Charles's the Saxon troops in 1702, a comedy was exhibited at Marienburg, where the combat was represented to the disadvantage of the Swedes. "Oh, (says Charles, hearing of it), I am far from envying them in this pleasure. Let them beat me upon the theatres as long as they will, provided I do but beat them in the field." He wrote some observations on war, and on his own campaigns from 1700 to 1709; but the MS. was lost at the unfortunate battle of Pultowa.

CHARLES'S-CAPE, a promontory of Virginia, in North America, forming the northern head-land of the strait that enters the bay of Chesapeake.

CHARLES'S-FORT, a fortress in the county of Cork, and province of Munster, in Ireland, situated at the mouth of Kinsale harbour. W. Long. 8. 20. and N. Lat. 51. 21.

CHARLES'S-TOWN, or *Charlestown*, the capital of South Carolina, in North America, situated on a peninsula formed by Ashley and Cooper rivers, the former of which is navigable for ships twenty miles above the town. W. Long. 79. 0. and N. Lat. 32. 30.

CHARLES'S-WAIN, in astronomy, seven stars in the constellation called *ursa major* or the Great Bear.

CHARLETON, an island at the bottom of Hudson's-bay, in North America, subject to Great Britain. W. Long. 80. 0. and N. Lat. 52. 30.

CHARLETON (Walter), a learned English physician born in 1619, was physician in ordinary to Charles I. and Charles II. one of the first members of the royal society, and president of the college of physicians. He wrote on various subjects; but at last his narrow circumstances obliged him to retire to the island of Jersey, where he died in 1707.

CHARLOCK, the English name of the *RAPHANUS*; it is a very troublesome weed among corn, being more frequent than almost any other. There are two principal kinds of it; the one with a yellow flower, the other with a white. Some fields are particularly subject to be over-run with it, especially those which have been manured with cow-dung alone, that being a manure very favourable to the growth of it. The farmers in some places are so sensible of this, that they always mix horse-dung with their cow-dung, when they use it for arable land. When barley, as is often the case, is infested with this weed to such a degree as to endanger the crop, it is a very good method to mow down the charlock in May, when it is in flower, cutting it so low as just to take off the tops of the leaves of barley with it: by this means the barley will get up above the weed; and people have got four quarters of grain from an acre of such land as would have scarce yielded any thing without this expedient. Where any land is particularly subject to this weed, the best method is to sow it with grass-seed, and make a pasture of it; for then the plant will not be troublesome, it never growing where there is a coat of grass upon the ground.

Queen CHARLOTTE'S ISLAND, an island in the South Sea, first discovered by captain Wallis in the Dolphin, in 1767, who took possession of it in the name of King George III. Here is good water, and plenty of cocoa-nuts, palm-nuts, and scurvy-grass. The inhabitants are of a middle stature, and dark complexion, with long hair hanging over their shoulders;

the men are well made, and the women handsome; their cloathing is a kind of coarse cloth, or matting, which they fasten about their middle.

Queen CHARLOTTE'S ISLANDS, a cluster of South-sea islands discovered in 1767 by captain Carteret. He counted seven, and there were supposed to be many more. The inhabitants of these islands are described as extremely nimble and vigorous, and almost as well qualified to live in the water as upon land: they are very warlike; and, on a quarrel with some of captain Carteret's people, they attacked them with great resolution; mortally wounded the master and three of the sailors; were not at all intimidated by the fire-arms; and at last, notwithstanding the aversion of captain Carteret to shed blood, he was obliged to secure the watering places by firing grape-shot into the woods, which destroyed many of the inhabitants. These islands lie in S. Lat. 11°. E. Long. 164°. They are supposed to be the Santa Cruz of Mandana, who died there in 1595.

CHARM, a term derived from the Latin *carmen*, a "verse;" and used to denote a magic power, or spell, by which, with the assistance of the devil, forcerers and witches were supposed to do wonderful things, far surpassing the power of nature.

CHARNEL, or *CHARNEL-HOUSE*, a kind of portico or gallery, usually in or near a church-yard, over which were anciently laid the bones of the dead, after the flesh was wholly consumed. Charnel-houses are now usually adjoining to the church.

CHARON, in fabulous history, the son of Erebus and Nox, whose office was to ferry the souls of the deceased over the waters of Acheron, for which each soul was to pay a piece of money. For this reason the Pagans had a custom of putting a piece of money into the mouth of the dead, in order that they might have something to pay Charon for their passage.

CHARONDAS, a celebrated legislator of the Thuriars, and a native of Catanea in Sicily, flourished 446 before Christ. He forbade any person's appearing armed in the public assemblies of the nation; but one day going thither in haste, without thinking of his sword, he was no sooner made to observe his mistake than he ran it through his body.

CHAROST, a town of France, in Berry, with the title of a duchy. It is seated on the river Arnon, E. Long. 2. 15. N. Lat. 46. 56.

CHAROUX, a town of France, in the Bourbonnois, seated on an eminence, near the river Sioulle. It has two parishes, which are in different dioceses. E. Long. 3. 15. N. Lat. 46. 10.

CHARPENTIER (Francis), dean of the French academy, was born in 1620. His early capacity inclined his friends to educate him for the bar: but he was much more delighted with the study of languages and antiquity than of the law; and preferred repose to tumult. M. Colbert made use of him in establishing his new academy of medals and inscriptions; and no person of that learned society contributed more than himself toward that noble series of medals which were struck on the considerable events that distinguished the reign of Louis XIV. He published several works, which were all well received; and died in 1702.

CHARR,

||
Charta.

CHARR, in ichthyology. See SALMO.

CHARRON (Peter), the author of a book intitled *Of Wisdom*, which gained him great reputation, was born at Paris in the year 1541. After being advocate in the parliament of Paris for five or six years, he applied himself to divinity; and became so great a preacher, that the bishops of several dioceses offered him the highest dignities in their gift. He died at Paris, suddenly in the street, November 16. 1603.

CHART, or SEA-CHART, an hydrographical map, or a projection of some part of the earth's superficies in *plano*, for the use of navigators.

Charts differ very considerably from geographical or land-maps, which are of no use in navigation. Nor are sea-charts all of the same kind, some being what we call plane-charts, others mercator-charts, and others globular charts.

Plane CHART, is a representation of some part of the superficies of the terraqueous globe, in which the meridians are supposed parallel to each other, the parallels of latitude at equal distances, and consequently the degrees of latitude and longitude every where equal to each other. See *PLANE Chart*.

Mercator's CHART, is that where the meridians are straight lines, parallel to each other, and equidistant; the parallels are also straight lines, and parallel to each other: but the distance between them increases from the equinoctial towards either pole, in the ratio of the secant of the latitude to the radius. See NAVIGATION.

Globular CHART, a meridional projection, wherein the distance of the eye from the plane of the meridian, upon which the projection is made, is supposed to be equal to the sine of the angle 45° . This projection comes the nearest of all to the nature of the globe, because the meridians therein are placed at equal distances; the parallels also are nearly equidistant, and consequently the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same as on the globe itself. See *GLOBULAR Projection*.

Hydrographic CHARTS, sheets of large paper, whereon several parts of the land and sea are described, with their respective coasts, harbours, sounds, flats, rocks, shelves, sands, &c. together with the longitude and latitude of each place, and the points of the compass. See *MERCATOR'S Chart*.

Selenographic CHARTS, particular descriptions of the spots, appearances, and maculae of the moon. See ASTRONOMY, n^o 63. and 140.

Topographic CHARTS, draughts of some small parts of the earth only, or of some particular places, without regard to its relative situation, as London, York, &c.

CHARTA, or CARTA, primarily signifies a sort of paper made of the plant *papyrus* or *biblus*. See PAPER, and CHARTER.

CHARTA Emporetica, in pharmacy, &c. a kind of paper made very soft and porous, used to filter withal. See FILTRATION, &c.

CHARTA is also used in our ancient customs for a charter, or deed in writing. See CHARTER.

Magna CHARTA, the great charter of the liberties of Britain, and the basis of our laws and privileges.

Charta.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state by charter: these liberties and privileges were also granted and confirmed by king Henry I. by a celebrated great charter now lost; but which was confirmed or re-enacted by king Henry II. and king John. Henry III. the successor of this last prince, after having caused 12 men make inquiry into the liberties of England in the reign of Henry I. granted a new charter; which was the same as the present magna charta. This he several times confirmed, and as often broke; till, in the 37th year of his reign, he went to Westminster-hall, and there, in presence of the nobility and bishops, who held lighted candles in their hands, magna charta was read, the king all the time holding his hand to his breast, and at last solemnly swearing faithfully and inviolably to observe all the things therein contained, &c. Then the bishops extinguishing the candles, and throwing them on the ground, they all cried out, "Thus let him be extinguished, and sink in hell, who violates this charter." It is observed, that, notwithstanding the solemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war against him; when, after various success, he confirmed this charter, and the charter of the forest, in the 52d year of his reign.

This charter confirmed many liberties of the church, and redressed many grievances incident to feudal tenures, of no small moment at the time; tho' now, unless considered attentively and with this retrospect, they seem but of trifling concern. But, besides these feudal provisions, care was also taken therein to protect the subject against other oppressions, then frequently arising from unreasonable amercements, from illegal distresses or other process for debts or services due to the crown, and from the tyrannical abuse of the prerogative of purveyance and pre-emption. It fixed the forfeiture of lands for felony in the same manner as it still remains; prohibited for the future the grants of exclusive fisheries; and the erection of new bridges so as to oppress the neighbourhood. With respect to private rights, it established the testamentary power of the subject over part of his personal estate, the rest being distributed among his wife and children; it laid down the law of dower, as it hath continued ever since; and prohibited the appeals of women, unless after the death of their husbands. In matters of public police and national concern, it enjoined an uniformity of weights and measures; gave new encouragements to commerce, by the protection of merchant-strangers; and forbade the alienation of lands in mortmain. With regard to the administration of justice: besides prohibiting all denials or delays of it, it fixed the court of common-pleas at Westminster, that the suitors might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trial of issues home to the very doors of the freeholders, by directing assizes to be taken in the proper counties, and establishing annual circuits: it also corrected some abuses then incident to the trials by wager of law and of battle; directed the regular awarding of inquests for life or member; prohibited the king's inferior ministers from holding pleas of the crown, or trying any criminal charge, whereby many for-

Charter,
Charter-
party.

forfeitures might otherwise have unjustly accrued to the exchequer; and regulated the time and place of holding the inferior tribunals of justice, the county-court, sheriff's torn, and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And lastly (which alone would have merited the title that it bears, of the *great charter*), it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unless declared to be forfeited by the judgment of his peers or the law of the land.

This excellent charter, so equitable, and beneficial to the subject, is the most ancient written law in the kingdom. By the 25th Edward I. it is ordained, that it shall be taken as the common law; and by the 43d Edward III. all statutes made against it are declared to be void.

CHARTER, in law, a written instrument, or evidence of things acted between one person and another. The word charter comes from the Latin *charta*, anciently used for a public and authentic act, a donation, contract, or the like; from the Greek *χαρτη*, "thick paper" or "pasteboard," whereon public acts were wont to be written. Britton divides charters into those of the king, and those of private persons. 1. Charters of the king, are those whereby the king passeth any grant to any person or body politic, as a *charter of exemption of privilege*, &c.; *charter of pardon*, whereby a man is forgiven a felony, or other offence committed against the king's crown and dignity; *charter of the forest*, wherein the laws of the forest are comprised, such as the charter of Canutus, &c. 2. Charters of private persons, are deeds and instruments for the conveyance of lands, &c. And the purchaser of lands shall have all the charters, deeds, and evidences, as incident to the same, and for the maintenance of his title.

CHARTER-Governments in America. See COLONY.

CHARTER-Land, such land as a person holds by charter; that is, by evidence in writing, otherwise called freehold.

CHARTERPARTY, in commerce, denotes the instrument of freightage, or articles of agreement for the hire of a vessel. See FREIGHT, &c.

The charterparty is to be in writing; and to be signed both by the proprietor or the master of the ship, and the merchant who freights it. It is to contain the name and the burden of the vessel; the names of the master and the freighter; the price or rate of freight; and the time of loading and unloading; and the other conditions agreed on. It is properly a deed, or policy, whereby the master or proprietor of the vessel engages to furnish immediately a tight sound vessel, well equipped, caulked, and stopped, provided with anchors, sails, cordage, and all other furniture to make the voyage required, as equipage, hands, victuals, and other munitions; in consideration of a certain sum to be paid by the merchant for the freight. Lastly, the ship with all its furniture, and the cargo, are respectively subjected to the conditions of the *charterparty*. The *charterparty* differs from a *bill of lading*, in that the first is for the entire freight, or lading, and that both for going and returning; whereas the latter is on-

Nº 69.

ly for a part of the freight, or at most only for the voyage one way.

The present Boyer says, the word comes from hence, that *per medium charta incidebatur, et sic fiebat charta partita*; because, in the time when notaries were less common, there was only one instrument made for both parties: this they cut in two, and gave each his portion; joining them together at their return, to know if each had done his part. This he observes to have been practised in his time; agreeable to the method of the Romans, who, in their stipulations, used to break a staff, each party retaining a moiety thereof as a mark.

CHARTOHPYLAX, the name of an officer of the church of Constantinople, who attends at the door of the rails when the sacrament is administered, and gives notice to the priests to come to the holy table. He represents the patriarch upon the bench, tries all ecclesiastical causes, keeps all the marriage registers, assists at the consecration of bishops, and presents the bishop elect at the solemnity, and likewise all other subordinate clergy. This office resembles in some shape that of the *bibliothecarius* at Rome.

CHARTRES, a large city of France, in the province of Orleanois, situated on the river Eure, in E. Long. 1. 32. N. Lat. 48. 47. It is a bishop's see.

CHARTREUSE, or CHARTREUSE-GRAND, a celebrated monastery, the capital of all the convents of the Carthusian monks, situated on a steep rock in the middle of a large forest of fir-trees, about seven miles north-east of Grenoble, in the province of Dauphine in France: E. Long. 5. 5. N. Lat. 45. 20. See CAR-THUSIANS.

From this mother-convent, all the others of the same order take their name; among which was the Chartreuse of London, corruptly called the charterhouse, now converted into an hospital, and endowed with a revenue of 600 l. *per ann.*

Here are maintained 80 decayed gentlemen, not under 50 years of age: also 40 boys are educated and fitted either for the university or trades. Those sent to the university, have an exhibition of 20 l. a-year for eight years; and have an immediate title to nine church-livings in the gift of the governors of the hospital, who are sixteen in number, all persons of the first distinction, and take their turns in the nomination of pensioners and scholars.

CHARTULARY, CHARTULARIUS, a title given to an ancient officer in the Latin church, who had the care of charters and papers relating to public affairs. The chartulary presided in ecclesiastical judgments, in lieu of the pope. In the Greek church the chartulary was called *chartophylax*; but his office was there much more considerable; and some even distinguish the chartulary from the *chartophylax* in the Greek church. See CHARTOPHYLAX.

CHARYBDIS, (anc. geog.) a whirlpool in the straits of Messina, according to the poets; near Sicily, and opposite to Scylla, a rock on the coast of Italy. Thucydides makes it to be only a strong flux and reflux in the strait, or a violent reciprocation of the tide, especially if the wind sets south. But on diving into the Charybdis, there are found vast gulphs and whirlpools

Chartohpy-
lax
||
Charybdis.

Chafe.

pools below, which produce all the commotion on the surface of the water.

Charybdis is used by Horace to denote a rapacious prostitute.

CHASE, or CHACE, in law, is used for a driving of cattle to or from any place; as to a distress, or forelet, &c.

CHASE, or *Chace*, is also a place of retreat for deer and wild beasts; of a middle kind between a forest and a park, being usually less than a forest, and not possessed of so many privileges; but wanting, *v. g.*

* See *Forest*. courts of attachment, swainmote, and justice-seat *.

Yet it is of a large extent, and stocked both with a greater diversity of wild beasts or game, and more keepers than a park. Crompton observes, that a forest cannot be in the hands of a subject, but it forthwith loses its name, and becomes a *chase*; in regard all those courts lose their nature when they come into the hands of a subject; and that none but a king can make a lord chief justice in eyre of the forest. See JUSTICE in *Eyre*.

British

Zool. i. 42.

The following history of the English chases is given by Mr Pennant. "At first the beasts of chase had this whole island for their range; they knew no other limits than the ocean, nor confessed any particular master. When the Saxons had established themselves in the heptarchy, they were reserved by each sovereign for his own particular diversion: hunting and war, in those uncivilized ages, were the only employ of the great; their active, but uncultivated minds, being susceptible of no pleasures but those of a violent kind, such as gave exercise to their bodies, and prevented the pain of thinking.

"But as the Saxon kings only appropriated those lands to the use of forests which were unoccupied, so no individuals received any injury: but when the conquest had settled the Norman line on the throne, this passion for the chase was carried to an excess, which involved every civil right in a general ruin: it superseded the consideration of religion even in a superstitious age: the village-communities, nay even the most sacred edifices, were turned into one vast waste, to make room for animals, the objects of a lawless tyrant's pleasure. The new forest in Hampshire is too trite an instance to be dwelt on; sanguinary laws were enacted to preserve the game; and in the reigns of William Rufus, and Henry I. it was less criminal to destroy one of the human species than a beast of chase. Thus it continued while the Norman line filled the throne; but when the Saxon line was restored under Henry II. the rigour of the forest laws was immediately softened.

"When our barons began to form a power, they claimed a vast, but more limited, tract for a diversion that the English were always fond of. They were very jealous of any encroachments on their respective bounds, which were often the cause of deadly feuds: such a one gave cause to the fatal day of *Chevy-chace*; a fact which, though recorded only in a ballad, may, from what we know of the manners of the times, be founded on truth: not that it was attended with all the circumstances which the author of that natural but heroic composition hath given it; for, on that day, neither a *Percy* nor a *Douglas* fell: here the poet

VOL. IV. Part I.

Chafe.

seems to have claimed his privilege, and mixed with this fray some of the events of the battle of *Otterbourne*.

"When property became happily more divided by the relaxation of the feudal tenures, these extensive hunting-grounds became more limited; and as tillage and husbandry increased, the beasts of chase were obliged to give way to others more useful to the community. The vast tracts of land, before dedicated to hunting, were then contracted; and, in proportion as the useful arts gained ground, either lost their original destination, or gave rise to the invention of *parks*. Liberty and the arts seem coeval; for when once the latter got footing, the former protected the labours of the industrious from being ruined by the licentious sportsman, or being devoured by the objects of his diversion: for this reason, the subjects of a despotic government still experience the inconveniences of vast wastes and forests, the terrors of the neighbouring husbandmen; while in our well regulated monarchy very few chases remain. The English still indulge themselves in the pleasures of hunting; but confine the deer-kind to parks, of which England boasts of more than any other kingdom in Europe. The laws allow every man his pleasure; but confine them in such bounds as prevent them from being injurious to the meanest of the community. Before the reformation, the prelates seem to have guarded sufficiently against this want of amusement, the see of Norwich, in particular, being possessed, about that time, of thirteen parks."

CHASE, in the sea-language, is to pursue a ship; which is also called *giving chase*.

Stern CHASE, is when the chaser follows the chased astern directly upon the same point of the compass.

To lie with a ship's fore-foot in a CHASE, is to sail and meet with her by the nearest distance; and so to cross her in her way, or to come across her fore-foot.

A ship is said to have a *good chase*, when she is so built foreward on, or a-stern, that she can carry many guns to shoot forewards or backwards; according to which she is said to have a *good foreward*, or *good stern chase*.

CHASE-GUNS, are such whose ports are either in the head (and then they are used in chasing of others); or in the stern, which are only useful when they are pursued or chased by any other ship.

CHASE of a Gun, is the whole bore or length of a piece taken within-side.

Wild-goose CHASE, a term used to express a sort of racing on horseback used formerly, which resembled the flying of wild-geese; those birds generally going in a train one after another, not in confused flocks as other birds do. In this sort of race the two horses, after running twelve score yards, had liberty, which horse soever could take the leading, to ride what ground the jockey pleased, the hindmost horse being bound to follow him within a certain distance agreed on by the articles, or else to be whipped in by the tryers and judges who rode by; and whichever horse could distance the other, won the race. This sort of racing was not long in common use; for it was found inhuman, and destructive to good horses, when two such were matched together. For in this case neither

Z z

was

Chasing
||
Chastity.

was able to distance the other till they were both ready to sink under their riders; and often two very good horses were both spoiled, and the wagers forced to be drawn at last. The mischief of this sort of racing soon brought in the method now in use, of running only for a certain quantity of ground, and determining the plate or wager by the coming in first at the post.

CHASING of Gold, Silver, &c. See ENCHASING.

CHASTE-TREE. See Vitex.

CHASTITY; purity of the body, or freedom from obscenity.—The Roman law justifies homicide in defence of the chastity either of one's self or relations; and so also, according to Selden, stood the law in the Jewish republic. Our law likewise justifies a woman for killing a man who attempts to ravish her. So the husband or father may justify killing a man who attempts a rape upon his wife or daughter; but not if he takes them in adultery by consent: for the one is forcible and felonious, but not the other.

Chastity is a virtue universally celebrated. There is indeed no charm in the female sex that can supply its place. Without it, beauty is unlovely, and rank is contemptible; good breeding degenerates into wantonness, and wit into impudence. Out of the numerous instances of eminent chastity recorded by authors, the two following are selected on account of the lesson afforded by the different modes of conduct which they exhibit.

Lucretia was a lady of great beauty and noble extraction: she married Collatinus, a relation of *Tarquinius Superbus*, king of Rome. During the siege of Ardea, which lasted much longer than was expected, the young princes passed their time in entertainments and diversions. One day as they were at supper*, at Sextus Tarquin's the king's eldest son, with Collatinus, *Lucretia's* husband, the conversation turned on the merit of their wives: every one gave his own the preference. "What signify so many words?" says Collatinus; "you may in a few hours, if you please, be convinced by your own eyes, how much my *Lucretia* excels the rest. We are young: let us mount our horses, and go and surprise them. Nothing can better decide our dispute than the state we shall find them in at a time when most certainly they will not expect us." They were a little warmed with wine: "Come on, let us go," they all cried together. They quickly galloped to Rome, which was about twenty miles from Ardea, where they find the princesses, wives of the young Tarquins, surrounded with company, and every circumstance of the highest mirth and pleasure. From thence they rode to Collatia, where they saw *Lucretia* in a very different situation. With her maids about her, she was at work in the inner part of her house, talking on the dangers to which her husband was exposed. The victory was adjudged to her unanimously. She received her guests with all possible politeness and civility. *Lucretia's* virtue, which should have commanded respect, was the very thing which kindled in the breast of Sextus Tarquin a strong and detestable passion. Within a few days he returned to Collatia; and upon the plausible excuse he made for his visit, he was received with all the politeness due to a near relation, and the eldest son of a king. Watching the fit-

test opportunity, he declares the passion she had excited at his last visit, and employed the most tender intreaties, and all the artifices possible, to touch a woman's heart; but all to no purpose. He then endeavoured to extort her compliance by the most terrible threatenings. *Lucretia* was in vain. She still persisted in her resolution; "could she be moved, even by the fear of death. But when the monster told her that he would first dispatch her, and then having murdered a slave, would lay him by her side, after which he would spread a report, that having caught them in the act of adultery, he had punished them as they deserved; this seemed to shake her resolution. She hesitated, not knowing which of these dreadful alternatives to take, whether, by consenting, to dishonour the bed of her husband, whom she tenderly loved; or, by refusing, to die under the odious character of having prostituted her person to the lust of a slave. He saw the struggle of her soul; and seizing the unlucky moment, obtained an inglorious conquest. Thus *Lucretia's* virtue, which had been proof against the fear of death, could not hold out against the fear of infamy. The young prince, having gratified his passion, returned home as in triumph. On the morrow, *Lucretia*, overwhelmed with grief and despair, sent early in the morning to desire her father and her husband to come to her, and bring with them each a trusty friend, assuring them there was no time to lose. They came with all speed, the one accompanied with *Valerius* (so famous after under the name of *Publicola*), and the other with *Brutus*. The moment she saw them come, she could not command her tears; and when her husband asked her if all was well? "By no means," said she, "it cannot be well with a woman after she has lost her honour. Yes, Collatinus, thy bed has been defiled by a stranger: but my body only is polluted; my mind is innocent, as my death shall witness. Promise me only not to suffer the adulterer to go unpunished: it is Sextus Tarquinus, who last night, treacherous guest, or rather cruel foe, offered me violence, and reaped a joy fatal to me; but, if you are men, it will be still more fatal to him." All promised to revenge her; and, at the same time, tried to comfort her with representing, "That the mind only sins, not the body; and where the consent is wanting, there can be no guilt." "What Sextus deserves," replies *Lucretia*, "I leave you to judge; but for me, though I declare myself innocent of the crime, I exempt not myself from punishment. No immodest woman shall plead *Lucretia's* example to outlive her dishonour." Thus saying, she plunged into her breast a dagger she had concealed under her robe, and expired at their feet. *Lucretia's* tragical death has been praised and extolled by Pagan writers, as the highest and most noble act of heroism. The gospel thinks not so: it is murder, even according to *Lucretia's* own principles, since she punished with death an innocent person, at least acknowledged as such by herself. She was ignorant that our life is not in our own power, but in his disposal from whom we receive it. *St Austin*, who carefully examines, in his book *De Civitate Dei*, what we are to think of *Lucretia's* death, considers it not as a courageous action, flowing from a true love of chastity, but as an infirmity of a woman too sensible of worldly fame and glory; and who, from

Chastity.

Briant.

a dread of appearing in the eyes of men an accomplice of the violence she abhorred, and of a crime to which she was entirely a stranger, commits a real crime upon herself voluntarily and designedly. But what cannot be sufficiently admired in this Roman lady is her abhorrence of adultery, which she seems to hold so detestable as not to bear the thoughts of it. In this sense, she is a noble example for all her sex.

Chiomara, the wife of Ortiagon, a Gaulish prince, was equally admirable for her beauty and chastity. During the war between the Romans and the Gauls, A. R. 563, the latter were totally defeated on Mount Olympus. *Chiomara*, among many other ladies, was taken prisoner, and committed to the care of a centurion, no less passionate for money than women. He, at first, endeavoured to gain her consent to his infamous desires; but not being able to prevail upon her, and subvert her constancy, he thought he might employ force with a woman whom misfortune had reduced to slavery. Afterwards, to make her amends for that treatment, he offered to restore her liberty; but not without ransom. He agreed with her for a certain sum, and to conceal this design from the other Romans, he permitted her to send any of the prisoners she should choose to her relations, and assigned a place near the river where the lady should be exchanged for gold. By accident there was one of her own slaves amongst the prisoners. Upon him she fixed; and the centurion soon after carried her beyond the advanced posts, under cover of a dark night. The next evening two of the relations of the princess came to the place appointed, whether the centurion also carried his captive. When they had delivered him the Attic talent they had brought, which was the sum they had agreed on, the lady, in her own language, ordered those who came to receive her to draw their swords and kill the centurion, who was then amusing himself with weighing the gold. Then, charmed with having revenged the injury done her chastity, she took the head of the officer, which she had cut off with her own hands, and hiding it under her robe, went to her husband Ortiagon, who had returned home after the defeat of his troops. As soon as she came into his presence, she threw the centurion's head at his feet. He was strangely surprised at such a sight; and asked her whose head it was, and what had induced her to do an act so uncommon to her sex? With a face covered with a sudden blush, and at the same time expressing her fierce indignation, she declared the outrage which had been done her, and the revenge she had taken for it. During the rest of her life, she stedfastly retained the same attachment for the purity of manners which constitutes the principal glory of the sex, and nobly sustained the honour of so glorious, bold, and heroic an action.—This lady was much more prudent than Lucretia, in revenging her injured honour by the death of her ravisher, rather than by her own. Plutarch relates this fact, in his treatise upon the virtue and great actions of women; and it is from him we have the name of this, which is well worthy of being transmitted to posterity.

The above virtue in men is termed *continence*. See CONTINENCE.

CHATEAU-BRIANT, a town of France in Brit-

tany, with an old castle. W. Long. 1. 20. N. Lat. 47. 40.

CHATEAU-*Chinon*, a town of France in Nivernois, and capital of Morvant, with a considerable manufacture of cloth. E. Long. 3. 48. N. Lat. 47. 2.

CHATEAU-*Dauphin*, a very strong castle of Piedmont in Italy, and in the marquisate of Saluces, belonging to the king of Sardinia. It was taken by the combined army of France and Spain in 1744, and was restored by the treaty of Aix-la-Chapelle.

CHATEAU-*du-Loir*, a town of France in the Maine, famous for sustaining a siege of seven years against the Count of Mans. It is seated on the river Loir, in E. Long. 0. 25. N. Lat. 47. 40.

CHATEAU-*Dun*, an ancient town of France, and capital of the Dunois, with a castle and rich monastery; seated on an eminence near the river Loir, in E. Long. 1. 26. N. Lat. 48. 4.

CHATEAU-*Neuf*, the name of several towns of France, viz. one in Perche; another in Angumois, on the river Charente, near Angoufeline; a third in Berry, seated on the river Cher; and several other small places.

CHATEAU-*Portien*, a town of France, in Champagne, and in a district called Portien, with a castle built on a rock, near the river Aine. E. Long. 4. 23. N. Lat. 49. 35.

CHATEAU-*Renaud*, a town of France, in the Gatenois, where clothes are made for the army, and where there is a trade in saffron. E. Long. 2. 25. N. Lat. 48. 0. This is also the name of a town of Touraine, in France, with the title of a marquisate. E. Long. 2. 41. N. Lat. 47. 22.

CHATEAU-*Roux*, a town of France, in Berry, with the title of a duchy. It has a cloth-manufacture, and is seated in a very large pleasant plain on the river Indre, in E. Long. 1. 47. N. Lat. 46. 49.

CHATEAU-*Thierra*, a town of France, in Champagne, with the title of a duchy, and a handsome castle on an eminence, seated on the river Maine, in E. Long. 3. 23. N. Lat. 49. 12.

CHATEAU-*Vilain*, a town of France, in Champagne, with a castle, and the title of a duchy; seated on the river Anjou. E. Long. 2. 59. N. Lat. 48. 0.

CHATEL, or CHATE, a town of Lorraine, in the Vosque, seated on the river Moselle, eight miles from Mirecourt.

CHATEL-*Aillon*, a maritime town of France, in Saintonge, five miles from Rochelle; formerly very considerable, but is now greatly decayed.

CHATEL-*Chalon*, a town of France, in Franche Comte, remarkable for its abbey of benedictine nuns. E. Long. 5. 25. N. Lat. 46. 50.

CHATELET, a town of the Netherlands, in Namur, seated on the Sambre, in the bishoprick of Liege. E. Long. 4. 28. N. Lat. 50. 25.

CHATELET, the name of certain courts of justice established in several cities in France. The grand chatelet at Paris, is the place where the presidial or ordinary court of justice of the provost of Paris is kept; consisting of a presidial, a civil chamber, a criminal chamber, and a chamber of policy. The little chatelet is an old fort, now serving as a prison.

CHATELLERAULT, a town of France, in Poi-

Château
||
Chatelle-
rault.

Chatham || Chatterton.
 Chatham town, with the title of a duchy; seated in a fertile and pleasant country, on the river Vienne, over which there is a handsome stone-bridge. E. Long. o. 40. N. Lat. 46. 34.

CHATHAM, a town of Kent, adjoining to Rochester, and seated on the river Medway. It is the principal station of the royal navy; and the yards and magazines are furnished with all kinds of naval stores, as well as materials for building and rigging the largest men of war. The entrance into the river Medway is defended by Sheerness and other forts; notwithstanding which, the Dutch fleet burnt several ships of war here in the reign of Charles II. after the peace of Breda had been agreed upon. In the year 1757, by direction of the Duke of Cumberland, several additional fortifications were begun at Chatham; so that now the ships are in no danger of an insult either by land or water. It has a church, a chapel of ease, and a ship used as a church for the sailors. It has likewise about 500 houses, mostly low, and built with brick; the streets are narrow, and paved; and it contains about 3000 inhabitants. The principal employment of the labouring hands is ship-building in the king's yard and private docks. This town gave title of Earl to that great statesman William Pitt in the reigns of George II. and III. E. Long. o. 40. N. Lat. 51. 20.

CHATIGAN, a town of Asia, in the kingdom of Bengal, on the most easterly branch of the river Ganges. It is but a poor place, though it was the first the Portuguese settled at in these parts, and who still keep a sort of possession. It has but a few cotton manufactures; but affords the best timber for building of any place about it. The inhabitants are so suspicious of each other, that they always go armed with a sword, pistol, and blunderbuss, not excepting the priests. It is subject to the Great Mogul. E. Long. 91. 10. N. Lat. 23. o.

CHATILLON-SUR-SEINE, a town of France, in Burgundy, divided into two by the river Seine. It is 32 miles from Langres, and 40 from Dijon; and has iron works in its neighbourhood. E. Long. 4. 33. N. Lat. 47. 45.

CHATRE, a town of France, in Berry, seated on the river Indres, 37 miles from Bourges. It carries on a considerable trade in cattle. E. Long. 1. 55. N. Lat. 46. 35.

CHATELS, a Norman term, under which were anciently comprehended all moveable goods; those immoveable being termed *fief*, or *fee*.

CHATELS, in the modern sense of the word, are all sorts of goods, moveable or immoveable, except such as are in the nature of freehold.

CHATTERER, in ornithology. See AMPELIS.

CHATTERTON (Thomas), a late unfortunate poet, whose fate and performances have excited in no small degree the public attention, as well as given rise to much literary controversy. He was born at Bristol, Nov. 20. 1752; and educated at a charity-school on St Augustin's Back, where nothing more was taught than reading, writing, and accounts. At 14 years of age, he was articled clerk to an attorney at Bristol, with whom he continued about three years; yet, though his education was thus confined, he discovered an early turn towards poetry and English antiquities, and par-

ticularly towards heraldry. How soon he began to be an author is not known. In the Town and Country Magazine for March 1769, are two letters, probably from him, as they are dated from Bristol, and subscribed with his usual signature, D. B. that is, *Dunhelmus Bristolensis*. The former contains short extracts from two MSS. "written 300 years ago by one Rowley a monk," concerning dress in the age of Henry II.; the latter, "Ethelgar, a Saxon poem," in bombast prose. In the same magazine for May 1769, are three communications from Bristol, with the same signature D. B. one of them intitled "Observations upon Saxon Heraldry, with drawings of Saxon Achievements;" and in the subsequent months of 1769 and 1770, there are several other pieces in the same magazine, which are undoubtedly of his composition.

In April 1770, he left Bristol, disgusted with his profession, and irreconcilable to the line of life in which he was placed; and coming to London in hopes of advancing his fortune by his pen, he sunk at once from the sublimity of his views to an absolute dependence on the patronage of booksellers. Things, however, seem soon to have brightened up a little with him; for, May 14. he writes to his mother, in high spirits, upon the change of his situation, with the following sarcastic reflection upon his former patrons at Bristol. "As to Mr —, Mr —, Mr —, &c. &c. they rate literary lumber so low, that I believe an author, in their estimation, must be poor indeed: but here matters are otherwise. Had Rowley been a Londoner instead of a Bristowyan, I could have lived by copying his works." In a letter to his sister, May 30, he informs her that he is to be employed in writing a voluminous History of London, to appear in numbers the beginning of next winter. Meanwhile, he had written something in praise of Beckford, then lord mayor, which had procured him the honour of being presented to his lordship; and, in the letter just mentioned, he gives the following account of his reception, with certain observations upon political writing. "The lord mayor received me as politely as a citizen could: but the devil of the matter is, there is no money to be got on this side of the question.—However, he is a poor author who cannot write on both sides.—Essays on the patriotic side will fetch no more than what the copy is sold for. As the patriots themselves are searching for places, they have no gratuity to spare.—On the other hand, unpopular essays will not even be accepted, and you must pay to have them printed: but then you seldom lose by it, as courtiers are so sensible of their deficiency in merit, that they generously reward all who know how to daub them with the appearance of it."

He continued to write incessantly in various periodical publications. July 11th, he tells his sister that he had pieces last month in several magazines; in The Gospel Magazine, The Town and Country, The Court and City, The London, The Political Register, &c. But all these exertions of his genius brought in so little profit, that he was soon reduced to the extremest indigence; so that at last, oppressed with poverty and also disease, in a fit of despair he put an end to his existence, Aug. 1770, with a dose of poison. This unfortunate person, though certainly a most extraordinary genius, seems yet to have been a most ungracious composition. He was violent and impetuous to a strange degree.

Chatterton. degree. From the first of the above-cited letters he seems to have had a portion of ill-humour and spleen more than enough for a lad of 17; and the editor of his *Miscellanies* records, "that he possessed all the vices and irregularities of youth, and that his profligacy was at least as conspicuous as his abilities."

In 1777 were published, in one volume 8vo, "Poems, supposed to have been written at Bristol, by Thomas Rowley and others, in the 15th century: the greatest part now first published from the most authentic copies, with an engraved specimen of one of the MSS. To which are added, a Preface, an introductory Account of the several Pieces, and a Glossary." And, in 1778, were published, in one volume 8vo, "Miscellanies in Prose and Verse, by Thomas Chatterton, the supposed author of the Poems published under the names of Rowley, &c."

Of Rowley's Poems, we have the following account in the preface, given in the words of Mr George Catcott of Bristol, to whom, it is said, the public is indebted for them. "The first discovery of certain MSS. having been deposited in Redcliff church above three centuries ago, was made in the year 1768, at the time of opening the new bridge at Bristol; and was owing to a publication in Farley's Weekly Journal, Oct. 1st, containing an account of the ceremonies observed at the opening of the old bridge, taken, as it was said, from a very ancient MS. This excited the curiosity of some persons to enquire after the original. The printer, Mr Farley, could give no account of it, or of the person who brought the copy; but after much inquiry it was discovered, that this person was a youth between 15 and 16 years of age, whose name was Thomas Chatterton, and whose family had been sextons of Redcliff church for near 150 years. His father, who was now dead, had also been master of the free-school in Pile-street. The young man was at first very unwilling to discover from whence he had the original: but, after many promises made to him, was at last prevailed on to acknowledge that he had received this, together with many other MSS. from his father, who had found them in a large chest in an upper room over the chapel, on the north side of Redcliff church." It is added, that soon after this Mr Catcott commenced an acquaintance with Chatterton, and partly as presents, partly as purchases, procured from him copies of many of his MSS. in prose and verse; as other copies were disposed of in like manner to others. It is concluded, however, that whatever may have been Chatterton's part in this very extraordinary transaction, whether he was the author, or only (as he constantly asserted) the copier of all these productions, he appears to have kept the secret entirely himself, and not to have put it in any one's power to bear certain testimony either of his fraud or of his veracity.

This affair, however, hath since become the foundation of a mighty controversy among the critics, which hath yet scarcely subsided. The poems in question, published in 1777, were republished in 1778, with an "Appendix, containing some observations upon their language; tending to prove that they were written, not by any ancient author, but entirely by Chatterton." Mr Warton, in the third volume of his *History of English poetry*, hath espoused the same side of the

question. Mr Walpole also obliged the world with a Letter on Chatterton, from his press at Strawberry-hill. On the other hand have appeared, "Observations" upon these poems, "in which their authenticity is ascertained," by Jacob Bryant, Esq. 1781, 2 vols 8vo; and another edition of the "Poems, with a Comment, in which their Antiquity is considered and defended, by Jeremiah Milles, D.D. Dean of Exeter, 1782," 4to. In answer to these two works, we have had three pamphlets: 1. "Curfory Observations on the Poems, and Remarks on the Commentaries of Mr Bryant and Dr Milles; with a salutary proposal addressed to the friends of those gentlemen." 2. "An Archæological Epistle to Dean Milles, editor of a superb edition of Rowley's Poems, &c." 3. "An Inquiry into the Authenticity of the Poems attributed to Thomas Rowley, in which the Arguments of the Dean of Exeter and Mr Bryant are examined, by Thomas Warton;" and other pieces in the public prints and magazines: All preparatory to the complete settlement of the business in "A Vindication of the Appendix to the Poems called Rowley's, in reply to the Answers of the Dean of Exeter, Jacob Bryant, Esq; and a third Anonymous Writer; with some further Observations upon those Poems, and an Examination of the Evidence which has been produced in support of their Authenticity. By Thomas Tyrwhitt, 1782," 8vo.

CHAUCER (Sir Geoffrey), an eminent English poet in the 14th century, born at London in 1328. After he left the university, he travelled into Holland, France, and other countries. Upon his return he entered himself in the Inner-temple, where he studied the municipal laws of England. His first station at court was page to Edward III. and he had a pension granted him by that prince till he could otherwise provide for him. Soon after we find him gentleman of the king's privy chamber; next year, shield-bearer to the king. Esteemed and honoured, he spent his younger days in a constant attendance at court, or for the most part living near it, in a square stone-house near the park-gate at Woodstock, still called *Chaucer's House*.

Soon after, having got the Duke of Lancaster for his patron, Chaucer began every day to rise in greatness. In 1373, he was sent, with other persons, to the republic of Genoa to hire ships for the king's navy (our want of shipping in those times being usually supplied by such means); and the king was so well satisfied with his negotiation, that, on his return, he obtained a grant of a pitcher of wine daily in the port of London, to be delivered by the butler of England; and soon after was made comptroller of the customs for wool, wool-fells, and hides; an office which he discharged with great diligence and integrity. At this period, Chaucer's income was about L. 1000 a-year; a sum which in those days might well enable him to live, as he says he did, with dignity in office, and hospitality among his friends. It was in this meridian blaze of prosperity, in perfect health of body and peace of mind, that he wrote his most humorous poems. His satires against the priests were probably written to oblige his patron the Duke of Lancaster, who favoured the cause of Wickliff, and endeavoured to expose the clergy to the indignation of the people. In the last year of Edward III. our poet was employed in a com-

mission

Chaucer. mission to treat with the French; and in the beginning of King Richard's reign, he was in some degree of favour at court.

The Duke of Lancaster at last finding his views checked, began to abandon Wickliffe's party: upon which Chaucer likewise, how much soever he had espoused that divine's opinions, thought it prudent to conceal them more than he had done. With the Duke's interest that of Chaucer entirely sunk; and the former passing over sea, his friends felt all the malice of the opposite party. These misfortunes occasioned his writing that excellent treatise *The Testament of Love*, in imitation of Boethius on the consolation of philosophy. Being much reduced, he retired to Woodstock, to comfort himself with study, which produced his admirable treatise of the *Astrolabe*.

The Duke of Lancaster at last surmounting his troubles, married Lady Catharine Swynford, sister to Chaucer's wife; so that Thomas Chaucer, our poet's son, became allied to most of the nobility, and to several of the kings of England. Now the sun began to shine upon Chaucer with an evening ray; for by the influence of the Duke's marriage, he again grew to a considerable share of wealth. But being now 70, he retired to Dunnington-castle near Newbury. He had not enjoyed this retirement long before Henry IV. son of the Duke of Lancaster, assumed the crown, and in the first year of his reign gave our poet marks of his favour. But however pleasing the change of affairs might be to him at first, he afterwards found no small inconveniences from it. The measures and grants of the late king were annulled; and Chaucer, in order to procure fresh grants of his pensions, left his retirement, and applied to court: where, though he gained a confirmation of some grants, yet the fatigue of attendance, and his great age, prevented him from enjoying them. He fell sick at London; and ended his days in the 72d year of his age, leaving the world as though he despised it, as appears from his song of *Flie from the Prese*. The year before his death he had the happiness, if at his time of life it might be so called, to see the son of his brother-in-law (Hen. IV.) seated on the throne. He was interred in Westminster abbey; and in 1556, Mr Nicholas Bingham, a gentleman of Oxford, at his own charge, erected a handsome monument for him there. Caxton first printed the *Canterbury Tales*; but his works were first collected and published in one volume folio, by William Thynne, London, 1542. They were afterwards reprinted in 1561, 1598, 1602. Oxford, 1721.

Chaucer was not only the first, but one of the best poets which these kingdoms ever produced. He was equally great in every species of poetry which he attempted; and his poems in general possess every kind of excellence, even to a modern reader, except melody and accuracy of measure; defects which are to be attributed to the imperfect state of our language, and the infancy of the art in this kingdom at the time when he wrote. "As he is the father of English poetry (says Mr Dryden), so I hold him in the same degree of veneration as the Grecians held Homer, or the Romans Virgil. He is a perpetual fountain of good sense, learned in all sciences, and therefore speaks properly on all subjects. As he knew what to say, so he knows also when to leave off; a continence which is practised by few

writers, and scarcely by any of the ancients, except Virgil and Horace." This character Chaucer certainly deserved. He had read a great deal; and was a man of the world, and of sound judgment. He was the first English poet who wrote *poetically*, as Dr Johnson observes in the preface to his Dictionary, and (he might have added) who wrote like a gentleman. He had also the merit of improving our language considerably, by the introduction and naturalization of words from the Provençal, at that time the most polished dialect in Europe.

CHAUCIS (anc. geog.), the country of the Chauci, a people of Germany: divided into the *Minores*, now *East Friesland* and the county of *Oldenburg*; and into the *Majores*, now the duchy of *Bremen* and a part of *Lunenbourg*.

CHAUD-MEDLEY, in law, is of much the same import with *CHANCE-Medley*. The former in its etymology signifies an affray in the heat of blood or passion; the latter, a casual affray. The latter is in common speech too often erroneously applied to any manner of homicide by misadventure; whereas it appears by the stat. 24 Hen. VIII. c. 5. and ancient books (Staundf. P. C. 16.), that it is properly applied to such killing as happens in self-defence upon sudden encounter.

CHAL, a town of the East Indies, on the coast of Malabar, in the province of Blagana, and kingdom of Visapour. Its river affords a good harbour for small vessels. The town is fortified, and so is the island on the south side of the harbour. It had formerly a good trade, but is now miserably poor. It was taken by the Portuguese in 1507, to whom it still belongs. It is 15 miles south of Bombay, and five miles from the sea. E. Long. 72. 45. N. Lat. 18. 30.

CHAULIEU (William Amfrye de), abbé d'Amale, one of the most polite and ingenious of the French poets, was born in 1639, and died at the age of 84. The most complete edition of his poems is that printed in 2 vols 8vo in 1733.

CHAUMONT, a town of France, in Champagne, and in the district of Bassigni, of which it is the capital. It is seated on a mountain near the river Marne. E. Long. 5. 15. N. Lat. 48. 6.

CHAUNE, a town of France, in Picardy, and in the district of Sansterre, with the title of a duchy. E. Long. 2. 55. N. Lat. 49. 45.

CHAUNTRY. See CHANTRY.

CHAUNY, a town of France, in Picardy, seated on the river Oise, in Chantry. E. Long. 3. 17. N. Lat. 49. 37.

CHAUVIN (Stephen), a celebrated minister of the reformed religion, born at Nismes, left France at the revocation of the edict of Nantz, and retired to Rotterdam, where he began a new *Journal des Sçavans*; and afterwards removing to Berlin, continued it there three years. At this last place, he was made professor of philosophy, and discharged that office with much honour and reputation. His principal work is a philosophical dictionary, in Latin, which he published at Rotterdam in 1692; and gave a new edition of it much augmented, at Lewarden, in 1713, folio. He died in 1725, aged 85.

CHAVEZ, a strong town of Tralos-Montes in Portugal, is seated at the foot of a mountain on the river Tamega. It has two suburbs, and as many forts; one

Chaucis

Chavez.

Chazelles, one of which looks like a citadel. Between the town and suburb of Magdalena, is an old Roman stone-bridge about 92 geometrical paces long. W. Long. 7. 1. N. Lat. 41. 45.

HAZELLES (John Matthew), a celebrated French mathematician and engineer, was born at Lyons in 1657. M. du Hamel, with whom he got acquainted, finding his genius incline towards astronomy, presented him to M. Cassini, who employed him in his observatory. In 1684, the Duke of Mortemar made use of Chazelles to teach him mathematics; and, the year after, procured him the preferment of hydrography professor for the galleys of Marseilles, where he set up a school for young pilots designed to serve aboard the galleys. In 1686, the galleys made four little campaigns, or rather four courses, purely for exercise. Chazelles went on board every time with them; kept his school upon the sea, and showed the practice of what he taught. In the year 1687 and 1688, he made two other sea-campaigns, in which he drew a great many plans of ports, roads, towns, and forts, which were lodged with the ministers of state. At the beginning of the war, which ended with the peace of Ryswick, some marine officers, and Chazelles among the rest, fancied the galleys might be so contrived as to live upon the ocean; that they might serve to tow the men of war when the wind failed or proved contrary, and also help to secure the coast of France upon the ocean. Chazelles was sent to the west coasts in July 1689, to examine the practicableness of this scheme; and in 1690, fifteen galleys new built set sail from Rochefort, and cruised as far as Torbay in England, and proved serviceable at the descent upon Tinmouth. After this, he digested into order the observations he had made on the coasts of the ocean; and drew distinct maps with a portulan to them, viz. a large description of every haven, of the depth, the tides, the dangers and advantages discovered, &c. These maps were inserted in the *Neptune Française*, published in 1692, in which year Chazelles was engineer at the descent at Oneille. In 1693, Monsieur de Pontchartrain, then secretary of state for the marine, and afterwards chancellor of France, resolved to get the *Neptune Française* carried on to a second volume, which was also to take in the Mediterranean. Chazelles desired that he might have a year's voyage on this sea, for making astronomical observations; and the request being granted, he passed by Greece, Egypt, and the other parts of Turkey, with his quadrant and telescope in his hand. When he was in Egypt he measured the pyramids; and finding the sides of the largest precisely facing the four cardinal points, naturally concluded this position to have been intended, and also that the poles of the earth and meridians had not since deviated. Chazelles likewise made a report of his voyage in the Levant, and gave the academy all the satisfaction they wanted concerning the position of Alexandria: upon which he was made a member of the academy in 1695. He died in 1710.

HAZINZARIANS, a sect of heretics who rose in Armenia in the seventh century. The word is formed of the Armenian *chazus*, "cross." They are also called *staurolatres*, which in Greek signifies the same as *Chazinarians* in Armenian, viz. adorers of the cross; they being charged with paying adoration to

the cross alone. In other respects they were Nestorians; and admitted two persons in Jesus Christ. Nicephorus ascribes other singularities to them; particularly their holding an annual feast in memory of the dog of their false prophet Sergius, which they called *artzibartzes*.

CHEASAPEAKE BAY, in North America, the entrance between Cape Henry and Cape Charles, running up 300 miles between Virginia and Maryland. It is navigable almost all the way for large ships, and has several navigable rivers that fall into it, by means of which ships go up to the very doors of the planters, to take in their lading of goods.—Here was a sea-engagement in 1781 between the British fleet under Admiral Graves consisting of 19 ships of the line, and the French fleet of 24 line-of-battle ships under the Count de Grasse, which ended in the Count's keeping possession of the Bay, by which Lord Cornwallis and his whole army were made prisoners of war at Yorktown, being invested both by sea and land by very superior numbers.

CHEATS, are deceitful practices in defrauding, or endeavouring to defraud, another of his known right, by means of some artful device, contrary to the plain rules of common honesty: as by playing with false dice, or by causing an illiterate person to execute a deed to his prejudice, by reading it over to him in words different from those in which it was written, &c.—If any person deceitfully get into his hands or possession any money or other things of any other person's by colour of any false token, &c. being convicted, he shall have such punishment by imprisonment, setting upon the pillory, or by any corporeal pain except pains of death, as shall be adjudged by the persons before whom he shall be convicted.—As there are frauds which may be relieved civilly, and not punished criminally; so there are other frauds which in a special case may not be helped civilly, and yet shall be punished criminally. Thus if a minor goes about the town, and, pretending to be of age, defrauds many persons by taking credit for a considerable quantity of goods, and then insisting on his nonage, the persons injured cannot recover the value of their goods, but they may indict and punish him for a common cheat. Persons convicted of obtaining money or goods by false pretences, or of sending threatening letters in order to extort money or goods, may be punished with fine or imprisonment, or by pillory, whipping, or transportation.

CHEBRECHIN, a town of Poland, in the province of Russia and palatinate of Belskow. It is seated on the declivity of a hill, and the river Wierpi waters its walls, and afterwards falls into the river Bog. The Jews there are very rich. E. Long. 23. 51. N. Lat. 50. 35.

CHECAYA, in Turkish affairs, the second officer of the Janizaries, who commands them under the aga, and is otherwise called *protogero*.

There is also a checaya of the treasury, stables, kitchen, &c. the word signifying as much as lieutenant, or the second in any office.

CHECK, or *CHECK-Roll*, a roll or book, wherein are contained the names of such persons as are attendants and in the pay of the king, or other great personages, as their household servants.

Cheasapeak
||
Check.

Check
||
Checks.

Clerk of the CHECK in the king's household, has the check and controlment of the yeomen of the guard, and all the ushers belonging to the royal family, allowing their absence or defects in attendance, or diminishing their wages for the same, &c. He also, by himself or deputy, takes the view of those that are to watch in the court, and has the setting of the watch, &c.

Clerk of the CHSECK in the royal dock-yards, an officer who keeps a muster or register of all the men employed aboard his majesty's ships and vessels, and also of all the artificers and others in the service of the navy at the port where he is settled.

CHECK, in falconry, a term used of a hawk, when she forsakes her proper game, to fly at pyes, crows, rooks, or the like, that cross her in her flight.

CHECKY, in heraldry, is when the shield, or a bordure, &c. is chequered, or divided into chequers or squares, in the manner of a chess-board.

This is one of the most noble and most ancient figures used in armoury; and a certain author saith, that it ought to be given to none but great warriors, in token of their bravery: for the chess-board represents a field of battle; and the pawns placed on both sides represent the soldiers of the two armies, which move, attack, advance, or retire, according to the will of the gamesters, who are the generals.

This figure is always composed of metal and colour. But some authors would have it reckoned among the several sorts of furs.

CHEEK, in anatomy, that part of the face situated below the eyes on each side.

CHEEKS, a general name among mechanics, for almost all those pieces of their machines and instruments, that are double, and perfectly alike. Thus, the cheeks of a printing-press are its two principal pieces: they are placed perpendicular, and parallel to each other; serving to sustain the three sommers, viz. the head, shelves, and winter, which bear the spindle, and other parts of the machine. See PRINTING-PRESS.

The *checks of a turner's lathe*, are two long pieces of wood, between which are placed the puppets, which are either pointed or otherwise, serving to support the work and the mandrils of the workman. These two pieces are placed parallel to the horizon, separated from one another by the thickness of the tail of the puppets, and joined with tenons to two other pieces of wood placed perpendicularly, called the *legs of the lathe*.

Checks of the glazier's vice, are two pieces of iron joined parallel at top and bottom; in which are the axis, or spindles, little wheel, cushions, &c. whereof the machine is composed.

The *cheeks of a mortar*, or the *brackets*, in artillery, are made of strong planks of wood, bound with thick plates of iron, and are fixed to the bed by four bolts; they rise on each side of the mortar, and to serve to keep her at what elevation is given her, by the help of strong bolts of iron which go through both cheeks, both under and behind the mortar, betwixt which are driven coins of wood; these bolts are called the *bracket-bolts*, and the bolts which are put one in each end of the bed, are the *traverse-bolts*, because with handspikes the mortar is by these traversed to the right or left.

CHEEKS, in ship-building, are two pieces of timber, fitted on each side of the mast at the top, serving to strengthen the masts there. The uppermost

bail or piece of timber in the beak of a ship, is called the *cheek*. The knees which fasten the beak-head to the ship, are called *cheeks*; and the sides of any block, or the sides of a ship's carriage of a gun, are called *cheeks*.

CHEESE, a sort of food prepared of curdled milk purged from the serum or whey, and afterwards dried for use.

Cheese differs in quality according as it is made from new or skimmed milk, from the curd which separates spontaneously upon standing, or that which is more speedily produced by the addition of rennet. Cream also affords a kind of cheese, but quite fat and butyraceous, and which does not keep long. Analyzed chemically, cheese appears to partake much more of an animal nature than butter, or the milk from which it was made. It is insoluble in every liquid except spirit of nitre, and caustic alkaline ley. Shaved thin, and properly treated with hot water, it forms a very strong cement if mixed with quicklime *. When * See *Chem. ment.* prepared with the hot water, it is recommended in the Swedish memoirs to be used by anglers as a bait: it may be made into any form, is not softened by the cold water, and the fishes are fond of it. — As a food, physicians condemn the too free use of cheese. When new, it is extremely difficult of digestion: when old, it becomes acrid and hot; and, from Dr Percival's experiments, is evidently of a septic nature. It is a common opinion that old cheese digests every thing, yet is left undigested itself; but this is without any solid foundation. Cheese made from the milk of sheep digests sooner than that from the milk of cows, but is less nourishing; that from the milk of goats digests sooner than either, but is also the least nourishing. In general, it is a kind of food fit only for the laborious, or those whose organs of digestion are strong.

Every country has places noted for this commodity: thus Chester and Gloucester cheese are famous in England; and the Parmesan cheese is in no less repute abroad, especially in France. This sort of cheese is entirely made of sweet cow-milk: but at Rochefort in Languedoc, they make it of ewe's milk; and in other places it is usual to add goat or ewe's milk in a certain proportion to that of the cow. There is likewise a kind of medicated cheese made by intimately mixing the expressed juice of certain herbs, as sage, baum, mint, &c. with the curd before it is fashioned into a cheese. — The Laplanders make a sort of cheese of the milk of their rein-deer; which is not only of great service to them as food, but on many other occasions. It is a very common thing in these climates to have a limb numbed and frozen with the cold: their remedy for this is the heating an iron red hot, and thrusting it through the middle of one of these cheeses; they catch what drops out, and with this anoint the limb, which soon recovers. They are subject also to coughs and diseases of the lungs, and these they cure by the same sort of medicine: they boil a large quantity of the cheese in the fresh deer's milk, and drink the decoction in large draughts warm several times a-day. They make a less strong decoction of the same kind also, which they use as their common drink, for three or four days together, at several times of the year. They do

Cheese.

Cheese

do this to prevent the mischiefs they are liable to from their water, which is otherwise their constant drink, and is not good.

The hundred weight of cheese pays on importation 1s. 3⁴/₁₀d. and draws back on exportation 1s. 1¹/₂d. at the rate of 6s. 8d.

Best methods of making Cheese in England. The double Gloucester is a cheese that pleases almost every palate. The best of this kind is made from new, or (as it is called in that and the adjoining counties) *covered milk*. An inferior sort is made from what is called *half-covered milk*; though when any of these cheeses turn out to be good, people are deceived, and often purchase them for the best *covered milk cheese*: but farmers who are honest have them stamped with a piece of wood made in the shape of a heart, so that any person may know them.

It will be every farmer's interest (if he has a sufficient number of cows) to make a large cheese from one meal's milk. This, when brought in warm, will be easily changed or turned with the rennet; but if the morning or night's milk be to be mixed with that which is fresh from the cow, it will be a longer time before it turns, nor will it change sometimes without being heated over the fire, by which it often gets dust or soot, or smoke, which will give the cheese a very disagreeable flavour.

When the milk is turned, the whey should be carefully strained from the curd. The curd should be broken small with the hands; and when it is equally broken, it must be put by little at a time into the vat, carefully breaking it as it is put in. The vat should be filled an inch or more above the brim, that when the whey is pressed out it may not shrink below the brim; if it does, the cheese will be worth very little. But first, before the curd is put in, a cheese-cloth or strainer should be laid at the bottom of the vat; and this should be so large, that when the vat is filled with the curd, the ends of the cloth may turn again over the top of it. When this is done, it should be taken to the press, and there remain for the space of two hours; when it should be turned and have a clean cloth put under it, and turned over as before. It must then be pressed again, and remain in the press six or eight hours; when it should again be turned and rubbed on each side with salt. After this it must be pressed again for the space of 12 or 14 hours more; when, if any of the edges project, they should be pared off: it may then be put on a dry board, where it should be regularly turned every day. It is a good way to have three or four holes bored round the lower part of the vat, that the whey may drain so perfectly from the cheese as not the least particle of it may remain.

The prevailing opinion of the people of Gloucestershire and the neighbouring counties is, that the cheeses will spoil if they do not scrape and wash them when they are found to be mouldy. But others think that suffering the mould to remain, mellows them, provided they are turned every day. Those, however, who will have the mould off, should cause it to be removed with a clean dry flannel, as the washing the cheeses is only a means of making the mould (which is a species of fungus rooted in the coat) grow again immediately.

Some people scald the curd: but this is a bad and mercenary practice; it robs the cheese of its fatness,

VOL. IV. Part I.

and can only be done with a view to raise a greater quantity of whey butter, or to bring the cheeses forward for sale, by making them appear older than they really are.

As most people like to purchase high-coloured cheese, it may be right to mix a little annatto with the milk before it is turned. No cheese will look yellow without it; and though it does not in the least add to the goodness, it is perfectly innocent in its nature and effects.

It is not in the power of any person to make good cheese with bad rennet; therefore the following receipt should be attended to. Let the *vell*, *maw*, *rennet-bag* (or by whatever name it is called), be perfectly sweet; for if it be the least tainted, the cheese will never be good. When this is fit for the purpose, three pints or two quarts of soft water (clean and sweet) should be mixed with salt, wherein should be put sweet-briar, rose leaves and flowers, cinnamon, mace, cloves, and, in short, almost every sort of spice and aromatic that can be procured; and if these are put into two quarts of water, they must boil gently till the liquor is reduced to three pints, and care should be taken that this liquor is not smoked. It should be strained clean from the spices, &c. and when found to be not warmer than milk from the cow, it should be poured upon the vell or maw. A lemon may then be sliced into it; when it may remain a day or two: After which it should be strained again, and put in a bottle; where, if well corked, it will keep good for twelve months or more. It will smell like a perfume; and a small quantity of it will turn the milk, and give the cheese a pleasing flavour. After this, if the vell be salted, and dried for a week or two near the fire, it will do for the purpose again almost as well as before.

Cheddar cheese is held in high esteem; but its goodness is said to be chiefly owing to the land whereon the cows feed, as the method of making it is the same as is pursued throughout Somersetshire, and the adjoining counties.

Cheshire cheese is much admired; yet no people take less pains with the rennet than the Cheshire farmers. But their cheeses are so large as often to exceed one hundred pounds weight each; to this (and the age they are kept, the richness of the land, and the keeping such a number of cows as to make such a cheese without adding a second meal's milk) their excellence may be attributed. Indeed they salt the curd (which may make a difference), and keep the cheeses in a damp place after they are made, and are very careful to turn them daily.

But of all the cheese this kingdom produces, none is more highly esteemed than the Stilton, which is called the *Parmesan* of England, and (except faulty) is never sold for less than 1s. or 1s. 2d. per pound.

The Stilton cheeses are usually made in square vats, and weigh from six to twelve pounds each cheese. Immediately after they are made, it is necessary to put them into square boxes made exactly to fit them; they being so extremely rich, that except this precaution be taken they are apt to bulge out, and break asunder. They should be continually and daily turned in these boxes, and must be kept two years before they are properly mellowed for sale.

Some make them in a net, somewhat like a cabbage net; so that they appear, when made, not unlike an a-

3 A

corn,

Cheese.

Cheese.

corn. But these are never so good as the other, having a thicker coat, and wanting all that rich flavour and mellowness which make them so pleasing.

It is proper to mention that the making of these cheeses is not confined to the Stilton farmers, as many others in Huntingdonshire (not forgetting Rutland and Northamptonshires) make a similar sort, sell them for the same price, and give all of them the name of *Stilton cheeses*.

Though these farmers are remarked for cleanliness, they take very little pains with the rennet, as they in general only cut pieces from the vell or maw, which they put into the milk, and move gently about with the hand, by which means it breaks or turns it so, that they easily obtain the curd. But if the method above described for making rennet were put in practice, they would make their cheese still better; at least they would not have so many faulty and unsound cheeses; for notwithstanding their cheeses bear such a name and price, they often find them so bad as not to be saleable; which is probably owing to their being so careless about the rennet.

It has been alleged, that as good cheese might be made in other counties, if people would adhere to the Stilton plan, which is this—They make a cheese every morning; and to this meal of new milk they add the cream taken from that which is milked the night before. This, and the age of their cheeses, have been supposed the only reasons why they are preferred to others; for from the nicest observation, it does not appear that their land is in any respect superior to that of other counties.

Excellent cream cheeses are made in Lincolnshire, by adding the cream of one meal's milk to milk which comes immediately from the cow; these are pressed gently two or three times, turned for a few days, and are then disposed of at the rate of 1s. per pound, to be eaten while new with radishes, sallad, &c.

Many people give skimmed milk to pigs, but the whey will do equally as well after cheeses are made from this milk; such cheeses will always sell for at least 2d. per pound, which will amount to a large sum annually where they make much butter. The peasants and many of the farmers in the north of England never eat any better cheese; and though they appear harder, experience hath proved them to be much easier of digestion than any new milk cheeses. A good market may always be found for the sale of them at Bristol.

Account of the making of Parmesan Cheese: by Mr Zappa of Milan, in answer to queries from Arthur Young, Esq.

“Are the cows regularly fed in stables?”—From the middle of April, or sooner if possible, the cows are sent to pasture in the meadows till the end of November usually.

“Or only fed in stables in winter?”—When the season is past, and snow comes, they are put into stables for the whole winter, and fed with hay.

“Do they remain in the pasture from morning till night? or only in hot weather?”—Between nine and ten in the morning the cows are sent to water, and then to the pastures, where they remain four or five hours at most, and at three or four o'clock are driven to the stables if the season is fresh, or under porticos if

hot; where, for the night, a convenient quantity of hay is given them.

“In what months are they kept at pasture the whole day?”—Mostly answered already; but it might be said, that no owner will leave his cattle, without great cause, in uncovered places at night. It happens only to the shepherds from the Alps, when they pass, because it is impossible to find stables for all their cattle.

“What is the opinion in the Lodofan, on the best conduct for profit in the management of meadows?”—For a dairy farm of 100 cows, which yields daily a cheese weighing 70 to 75 lb. of 28 ounces, are wanted 1000 perticas of land. Of these about 800 are standing meadows, the other 200 are in cultivation for corn and grass fields in rotation.

“Do they milk the cows morning and evening?”—Those that are in milk are milked morning and evening, with exception of such as are near calving.

“One hundred cows being wanted to make a Lodofan each day, it is supposed that it is made with the milk of the evening and the following morning; or of the morning and evening of the same day: how is it?”—The 100 cows form a dairy farm of a good large cheese; it is reckoned that 80 are in milk, and 20 with calves sucking, or near calving. They reckon one with the other about 32 boccalis of 32 oz. of milk. Such is the quantity for a cheese of about 70 lb. of 28 ounces. They join the evening with the morning milk, because so it is fresher than if it was that of the morning and evening of the same day. The morning milk would be 24 hours old when the next morning the cheese should be made.

“Do they skim or not the milk to make butter before they make the cheese?”—From the evening milk all the cream possible is taken away for butter, mascarponi (cream-cheese), &c. The milk of the morning ought to be skimmed slightly; but every one skims as much cream as he can. The butter is sold on the spot immediately at 24 sous; the cheese at about 28 sous. The butter loses nothing in weight; the cheese loses one-third of it, is subject to heat, and requires expences of service, attention, warehouses, &c. before it is sold; and a man in two hours makes 45 to 50 lb. of butter that is sold directly. However, it is not possible to leave much cream in the milk to make Lodofan cheese, called *grained cheese*; because if it is too rich, it does not last long, and it is necessary to consume it while young and sound.

“Is Parmesan or Lodofan cheese made every day in the year or not?”—With 100 cows it is. In winter, however, the milk being less in quantity, the cheese is of lesser weight, but certainly more delicate.

“After gathering or uniting the milk, either skimmed or not, what is exactly the whole operation?”—The morning of the 3d of March 1786, I have seen the whole operation, having gone on purpose to the spot to see the whole work from beginning to end. At 16 Italian hours, or ten in the morning, according to the northern way to account hours, the skimming of that morning's milk, gathered only two hours before, was finished. I did, meanwhile, examine the boiler or pot. At the top it was eight feet (English) diameter, or thereabout; and about five feet three inches deep, made

Cheese.

Cheese.

made like a bell, and narrowing towards the bottom to about two one-half feet. They joined the cream produced that morning with the other produced by the milk of the evening before. That produced by this last milk was double in quantity to that of the morning milk, because it had the whole night to unite, and that of the morning had only two hours to do it, in which it could not separate much. Of the cream some was destined to make mascarponies (cream-cheese), and they put the rest into the machine for making butter. Out of the milk of the evening before and of that morning that was all put together after skimming, they took and put into the boiler 272 boccali, and they put under it two faggots of wood; which being burnt, were sufficient to give the milk a warmth a little superior to lukewarm. Then the boiler being withdrawn from the fire, the foreman put into it the rennet, which they prepare in small balls of one ounce each, turning the ball in his hand always kept in the milk entirely covered; and after it was perfectly dissolved, he covered the boiler to keep the milk defended, that it might not suffer from the coldness of the season, in particular as it was a windy day. I went then to look on the man that was making mascarponies, &c. and then we went twice to examine if the milk was sufficiently coagulated. At the 18 hours, according to the Italian clocks, or noon, the true manufactory of cheese began. The milk was coagulated in a manner to be taken from the boiler in pieces from the surface. The foreman, with a stick that had 18 points, or rather nine small pieces of wood fixed by their middle in the end of it, and forming nine points in each side, began to break exactly all the coagulated milk, and did continue to do so for more than half an hour, from time to time examining it to see its state. He ordered to renew the fire, and four faggots of willow branches were used all at once: he turned the boiler that the fire might act; and then the underman began to work in the milk with a stick like the above, but with only four smaller sticks at the top, forming eight points, four at each side, a span long each point. In a quarter of an hour the foreman mixed in the boiler the proper quantity of saffron, and the milk was all in knobs, and finer grained than before, by the effect of turning and breaking the coagulation, or curd, continually. Every moment the fire was renewed or fed; but with a faggot only at a time, to continue it regular. The milk was never heated much, nor does it hinder to keep the hand in it to know the fineness of the grain, which refines continually by the flick-work of the underman. It is of the greatest consequence to mind when the grain begins to take a consistence. When it comes to this state, the boiler is turned from the fire, and the underman immediately takes out the whey, putting it into proper receivers. In that manner the grain subsides to the bottom of the boiler; and leaving only in it whey enough to keep the grain covered a little, the foreman extending himself as much as he can over and in the boiler, unites with his hands the grained milk, making like a body of paste of it. Then a large piece of linen is run by him under that paste, while another man keeps the four corners of it, and the whey is directly put again into the boiler, by which is facilitated the means of raising that paste that is taken out of the boiler, and put for one quarter of an hour into the receiver where the whey

was put before, in the same linen it was taken from the boiler; which boiler is turned again directly on the fire, to extract the mascarpa (whey-cheese); and is a second product, eaten by poor people. After the paste remained for a quarter of an hour in that receiver, it was taken out and turned into the wooden form called *fassera*, without any thing else made than the roundity, having neither top or bottom. Immediately after having turned it into that round wooden form, they put a piece of wood like a cheese on it, putting and increasing gradually weights on it, which serve to force out the remnant of whey; and in the evening the cheese so formed is carried into the warehouse, where, after 24 hours, they begin to give the salt. It remains in that warehouse for 15 or 20 days; but in summer only from 8 to 12 days. Meanwhile the air and salt form the crust to it; and then it is carried into another warehouse for a different service. In the second warehouse they turn every day all the cheeses that are not older than six months; and afterwards it is enough if they are only turned every 48 or 60 hours, keeping them clean, in particular of that bloom which is inevitable to them, and which, if neglected, turns musty, and causes the cheese to acquire a bad smell. The Lodofan, because it is a province watered, has a great deal of meadows, and abounds with cows, its product being mostly in cheese, butter, &c. However, the province of Pavia makes a great deal of that cheese; and we Milanese do likewise the same from the side of Porte Tosa, Romana, Ticinese, and Vercellina, because we have fine meadows and dairy farms.

CHEESE-Rennet. See GALLIUM and RUNNET.

CHEGOE, or **NIGUA**, the Indian name of an insect common in Mexico, and also found in other hot countries where it is called *pique*, is an exceeding small animal, not very unlike a flea, and is bred in the dust. It fixes upon the feet, and breaking insensibly the cuticle, it nestles betwixt that and the true skin, which also, unless it is immediately taken out, it breaks, and pierces at last to the flesh, multiplying with a rapidity almost incredible. It is seldom discovered until it pierces the true skin, when it causes an intolerable itching. These insects, with their astonishing multiplication, would soon dispeople those countries, were it less easy to avoid them, or were the inhabitants less dexterous in getting them out before they begin to spread. On the other hand, nature, in order to lessen the evil, has not only denied them wings, but even that conformation of the legs and those strong muscles which are given to the flea for leaping. The poor, however, who are in some measure doomed to live in the dust, and to a habitual neglect of their persons, suffer these insects sometimes to multiply so far as to make large holes in their flesh, and even to occasion dangerous wounds.

CHEIRANTHUS, **STOCK-GILLIFLOWER**, or *Wall-flower*: A genus of the 39th natural order, *Siliquosæ*; and belonging to the tetradynamia class of plants. The germen is marked with a glandulous denticle on each side; the calyx is close, with two of its leaves gibbous at the base; the seeds plane. The species are 13; but the following three are most worthy of notice. 1. The cheiri, or common wall-flower, with ligneous, long, tough roots; an upright, woody, abiding stalk, divided into many erect angular branches, forming a bushy head from one to two feet high, closely garnished with

Cheese
||
Cheiran-
thus.

Cheiran-
thus
||
Cheke.

spear-shaped, acute, smooth leaves, and all the branches terminating in long erect spikes of numerous flowers, which in different varieties are yellow, bloody, white, &c. 2. The incanus, or hoary cheiranthus, with ligneous, long, naked, white roots; and upright, strong, woody, abiding stem, from one to three feet high, branchy at top, adorned with long, spear-shaped, obtuse, hoary leaves; and the top of the stalk and all the branches terminated by erect spikes of flowers from one to two or three feet long, of different colours in different varieties. 3. The annuus, or ten-weeks-stock, with an upright, woody, smooth stalk, divided into a branchy head, 12 or 15 inches high, garnished with spear-shaped, blunt, hoary leaves, a little indented, and all the branches terminated by long erect spikes of numerous flowers of different colours in different varieties.—The two first sorts are very hardy evergreen biennials or perennials; but the last is an annual plant, so must be continued by seed sown every year; and even the two first, notwithstanding their being perennial, degenerate so much in their flowers after the first year, that it will be proper also to raise an annual supply of them. The seeds are to be saved only from the plants with single flowers; for the double ones bring no seeds to perfection. The seeds are to be chosen from such flowers as have five, six, or more petals, or from such as grow near to the double ones. They may be sown in the full ground in the spring, and may be afterwards transplanted. When fine doubles of the two first kinds are obtained, they may be multiplied by slips from the old plants.

CHEKAO, in natural history, the name of an earth found in many parts of the East Indies, and sometimes used by the Chinese in their porcelain manufactures. It is a hard and stony earth; and the manner of using it is this: they first calcine it in an open furnace, and then beat it to a fine powder. This powder they mix with large quantities of water: then stirring the whole together, they let the coarser part subside; and pouring off the rest yet thick as cream, they leave it to settle, and use the matter which is found at the bottom in form of a soft paste, and will retain that humidity a long time. This supplies the place of the earth called *hoache*, in the making of that elegant sort of china-ware which is all white, and has flowers which seem formed by a mere vapour within its surface. The manner of their using it is this: they first make the vessel of the common matter of the manufacture; when this is almost dry, they paint upon it the flowers, or whatever other figures they please, with a pencil dipped in this preparation of the chekao; when this is thoroughly dry, they cover the whole vessel with the varnish in the common way, and bake it as usual. The consequence is, that the whole is white: but the body of the vessel, the figures, and the varnish, being three different substances, each has its own particular white; and the flowers being painted in the finest white of all, are distinctly seen through the varnish upon the vessel, and seem as if traced by a vapour only. The *hoache* does this as well as the chekao; and has besides his the quality of serving for making the porcelain ware either alone, or in the place of kaolin: the chekao has not this property, nor any other substance besides this *hoache*, which appears to be the same with our steatites or soap-rock.

CHEKE (Sir John), a celebrated statesman, gram-

marian, and divine, of an ancient family in the isle of Wight, was born at Cambridge in the year 1514, and educated at St John's college in that university; where, after taking his degrees in arts, he was first chosen Greek lecturer, and in 1540 professor of that language, with a stipend of 40 l. a-year. In this station he was principally instrumental in reforming the pronunciation of the Greek language, which, having been much neglected, was imperfectly understood. About the year 1543 he was incorporated master of arts at Oxford, where, we are told, he had studied for some time. In the following year he was sent to the court of king Henry VIII. and appointed tutor for the Latin language, jointly with Sir Anthony Cooke, to prince Edward, about which time he was made canon of the college newly founded in Oxford; wherefore he must have now been in orders. On the accession of his royal pupil to the crown, Mr Cheke was first rewarded with a pension of 100 merks, and afterwards obtained several considerable grants from the crown. In 1550 he was made chief gentleman of the privy-chamber, and was knighted the following year; in 1552, chamberlain of the exchequer for life; in 1553, clerk of the council; and soon after secretary of state and privy-councillor. But these honours were of short duration. Having concurred in the measures of the duke of Northumberland for settling the crown on the unfortunate Jane Grey, and acted as her secretary during the nine days of her reign, on the accession of queen Mary, Sir John Cheke was sent to the tower, and stripped of the greatest part of his possessions. In September 1554 he obtained his liberty, and a licence from her majesty to travel abroad. He went first to Basil, thence to Italy, and afterwards returned to Strasburg, where he was reduced to the necessity of reading Greek lectures for subsistence. In 1556 he set out in an evil hour to meet his wife at Brussels: but, before he reached that city, he was seized by order of king Philip II. hoodwinked, and thrown into a waggon; and thus ignominiously conducted to a ship, which brought him to the tower of London. He soon found that religion was the cause of his imprisonment; for he was immediately visited by two Romish priests, who piously endeavoured to convert him, but without success. However, he was at last visited by Fleckenham; who told him from the queen, that he must either comply or burn. This powerful argument had the desired effect; and Sir John Cheke accordingly complied in form, and his lands, upon certain conditions, were restored: but his remorse soon put an end to his life. He died in September 1557, at the house of his friend Mr Peter Osborne in Woodstreet, London, and was buried in St Alban's church. He left three sons, the eldest of whom, Henry, was knighted by queen Elizabeth. He wrote 1. A Latin translation of two of St Chrysostom's homilies. Lond. 1543, 4to. 2. The Hurt of Sedition. Lond. 1549, 1576, 1641. 3. Latin Translation of the English Communion Service. Printed among Bucer's opuscula. 4. De pronunciatione Græcæ. Basil, 1555, 8vo. 5. Several letters published in his life by Strype; and a great number of other books.

CHE-KYANG, or TCHE-KIANG, a maritime province of China, and one of the most considerable in the empire; is bounded on the south by Fo-kien; on the north and west by Kiang-nan and Kiangsi; and

Cheke,
Che-kyang.

Che-kyang on the east by the sea. The air is pure and healthful, and the soil fertile, being watered by a number of rivers and canals, as well as springs and lakes. The chief produce is silk; a vast quantity of which is cultivated here, and for which the whole country is covered with mulberry trees. These are purposely checked in their growth by the natives, experience having taught them, that the leaves of the smallest trees produce the best silk. The stuffs made in this province, which are embroidered with gold and silver, are reckoned the best in the empire: and notwithstanding a vast exportation to the Japan and Philippine islands, as well as to every part of China, and to Europe, such an abundance is left in the province, that a complete suit of silk may be bought here as cheap as one of the coarsest woollen in France.

This province is also remarkable for a particular species of mushrooms, which is exported to every part of the empire. They are pickled, and then dried; when they will keep good for a whole year. When used they must be soaked in water, which renders them as fresh as at first. Here also the tallow tree is met with; and the province affords excellent hams, and those small gold-fishes with which the ponds are usually stocked.

Che-kyang contains 11 cities of the first class, 72 of the third, and 18 fortresses, which, in Europe, would be accounted large cities. The principal of these are, 1. Hang-tcheou-fou, the metropolis, accounted by the Chinese to be the paradise of the earth. It is four leagues in circumference, exclusive of the suburbs; and the number of its inhabitants are computed at more than a million, and 10,000 workmen are supposed to be employed within its walls in manufacturing of silk. Its principal beauty is a small lake, close to the walls on the western side, the water of which is pure and limpid, and the banks almost every where covered with flowers. Its banks are likewise adorned with halls and open galleries supported by pillars, and paved with large flag-stones for the convenience of those who are fond of walking; and the lake itself is intersected with causeways cased with cut-stone, openings covered with bridges being left in them for the passage of boats. In the middle are two islands with a temple and several pleasure-houses, and the emperor has a small palace in the neighbourhood. The city is garrisoned by 3000 Chinese and as many Tartars, and has under its jurisdiction seven cities of the third class. 2. Hou-tcheou-fou is also situated on a lake, and manufactures an incredible quantity of silk, inasmuch, that the tribute of a city under its jurisdiction amounts to more than 500,000 ounces of silver. 3. Ning-po-fou, by Europeans called Liampo, is an excellent port, opposite to Japan. Eighteen or twenty leagues from it is an island called Tcheou-chan, where the English first landed on their arrival at China. 4. Ning-po is remarkable for the silk manufactured there, which is much esteemed in foreign countries, especially Japan, where it is exchanged for gold, silver, and copper. 5. Chao-hing-fou, situated in an extensive and fertile plain, is remarkable for a tomb about half a league distant, which is said to be that of Yu. The people of this province are said to be the most versed in chicanery of any in China. 6. Tchu-tcheou-fou, remarkable for having in its neighbourhood pines of an extraordinary size, capable of containing 40 men in their trunks. The

inhabitants are ingenious, polite, and courteous to strangers, but very superstitious.

CHELIDONIAS, according to Pliny, an anniversary wind, blowing at the appearance of the swallows; otherwise the Favonius, or Zephyrus.

CHELIDONIUM, CELANDINE, and HORNED or PRICKLY POPPY: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 27th order, *Rhæadæa*. The corolla is tetrapetalous, the calyx diphyllous, the filiqua unilocular and linear. There are six species, none of which are remarkable for their beauty; but one of them, viz. the majus, is an article in the materia medica. It grows on old walls, among rubbish, and in waste shady places. The herb is of a bluish green colour; the root of a deep red; and both contain a gold-coloured juice: their smell is disagreeable, the taste somewhat bitterish, very acrid, burning and biting the mouth; the root is the most acrid. The juice takes off warts; cures tetters, ring-worms, and the itch; and, diluted with milk, it consumes opaque white spots on the eye.—Horses, cows, goats, and swine, refuse to eat the herb.

CHELIDONIUS LAPIS, in natural history, a stone said by the ancients to be found in the stomachs of young swallows, and greatly cried up for its virtues in the falling-sickness; but, from their description, it appears to be only a species of lycodontes, or bufonitæ. See LYCODONTES, and BUFONITÆ.

CHELM, a town of Poland, capital of a palatinate of the same name. It is situated in the province of Red Russia. E. Long. 23. 30. N. Lat. 51. 25.

CHELMSFORD, the county town of Essex, situated on the river Chelmer, in E. Long. 0. 30. N. Lat. 51. 40. It sends two members to parliament.

CHELONE, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personate*. The calyx is quinquepartite; the rudiment of a fifth filament among the highest stamina, the capsule bilocular. There are three species, viz. the Glabra, the Hirsuta, and the Penstemon. They are natives of North America; and are herbaceous flowery perennials, with upright stalks two feet high, decorated with spear-shaped leaves, and beautiful spikes of monopetalous, ringent flowers, red, rose-coloured, blue, and purple. They flower from September to November, and are sometimes succeeded by ripe seeds in this country. They are very hardy plants, and may be propagated by seeds sown in any soil or situation; but the two first multiply so fast by their creeping roots, that the seeds are seldom regarded.

CHELSEA, a fine village situated on the northern bank of the river Thames, a mile westward of Westminster, remarkable for a magnificent hospital of invalids and old decrepit soldiers; and a pleasure-house, called Ranelagh, to which a great deal of fine company resort in summer; and a noble botanic garden belonging to the company of apothecaries. The royal hospital of invalids was begun by Charles II. carried on by James II. and finished by king William. It consists of a vast range of buildings, that form three large squares, in which there is an uncommon air of neatness and elegance observed. It is under the direction of commissioners, who consist generally of the

Chelidoniae
||
Chelsea.

Chelsea.

officers of state and of war. There is a governor with 500 l. salary, a lieutenant governor with 400 l. and a major, with 250 l. besides inferior officers, serjeants, corporals and drums, with about 400 men, who all do garrison duty; and there are above 10,000 out pensioners who receive an annuity of 7 l. 12 s. 6 d. each; all which expence is defrayed by a poundage deducted from the army, deficiencies being made good by parliament.—The botanic garden is very extensive, enriched with a vast variety of domestic and exotic plants, the original stock of which was given to the apothecaries of London by Sir Hans Sloane.—At Ranelagh Garden and amphitheatre the entertainment is a fine band of music, with an organ and

some of the best voices, and the regale is tea and coffee.

CHELTENHAM, or CHILTENHAM, a market town of Gloucestershire, seven miles north-east of Gloucester. W. Long. 2. 10. N. Lat. 51. 50. It is chiefly remarkable for its mineral waters, of the same kind with those of Scarborough. See SCARBOROUGH.

CHEMISE, in fortification, the wall with which a bastion, or any other bulwark of earth, is lined for its greater support and strength: or it is the solidity of the wall from the talus to the stone-row.

Fire-CHEMISE, a piece of linen cloth, steeped in a composition of oil of petrol, camphor, and other combustible matters, used at sea, to set fire to an enemy's vessel.

Cheltenham.
Chemise.

C H E M I S T R Y

Definition.

MAY be defined, The study of such phenomena or properties of bodies as are discovered by variously mixing them together, and by exposing them to different degrees of heat, alone, or in mixture, with a view to the enlargement of our knowledge in nature, and to the improvement of the useful arts: or, It is the study of the effects of heat and mixture upon all bodies, whether natural or artificial, with a view to the improvement of arts and natural knowledge.

Antiquity.

The science of chemistry is undoubtedly of very high antiquity; and, like most other sciences, its origin cannot be traced. In scripture, Tubal Cain, the 8th from Adam, is mentioned as the father or instructor of every artificer in brass or iron. This, however, does not constitute him a chemist, any more than a founder or blacksmith among us has a right to that title. The name of chemist could only belong to him, whoever he was, who first discovered the method of extracting metals from their ores; and this person must necessarily have lived before Tubal Cain, as every blacksmith or founder must have metals ready prepared to his hand. Nevertheless, as Tubal Cain lived before the flood, and the science of chemistry must have existed before his time, some have conjectured, that the metallurgic part, on account of its extreme usefulness to mankind, was revealed to Adam by God himself.

3
Science
founded.

Be this as it will, *Siphoas*, an Egyptian, is considered by the chemists as the founder of their science. He was known by the Greeks under the name of *Hermes*, or *Mercurius Trismegistus*; and is supposed to have lived more than 1900 years before the Christian æra. A numerous list of this philosopher's works is given by Clemens Alexandrinus; but none of them are now to be found, nor do any of them appear to have been written professedly on chemistry.

Two illustrious Egyptians, of the name of *Hermes*, are recorded by ancient authors. The elder supposed to be the same with *Mizraim*, the grandson of Noah, the *Hermes* of the Greeks, and *Mercury* of the Romans. The younger *Hermes* lived a thousand years afterwards; and is supposed to have restored the sciences after they had fallen into oblivion, in consequence of an inundation of the Nile. No less than

36,000 books are said to have been written under the name of *Hermes*; but, according to Jamblichus, a custom prevailed of inscribing all books of science with the name of *Hermes*. Some authors deny the existence of *Hermes*, and maintain that his history is allegorical.

As the science of chemistry is supposed to have been well known to the Egyptians, *Moses*, who was skilled in their wisdom, is thence ranked among the number of chemists; a proof of whose skill in this science is thought to be, his dissolving the golden calf made by the Israelites, so as to render it potable.

4
Moses sup-
posed to be
skilled in
chemistry.

Of all the Greeks who travelled into Egypt in order to acquire knowledge, *Democritus* alone was admitted into their mysteries. The Egyptian priests are said to have taught him many chemical operations; among which were the art of softening ivory, of vitrifying flints, and of imitating precious stones. Dr Black, however, is of opinion, that *Democritus* knew nothing more of these arts than that of making a coarse kind of glass, as no mention is particularly made of his imitating any other precious stone than the emerald, whose colour is green; and the coarser the glass the greener it is.

After the time of *Democritus*, we may know that considerable improvements were made in chemistry, as physicians began to make use of metallic preparations, as ceruse, verdegris, litharge, &c. *Dioscorides* describes the distillation of mercury from cinnabar by means of an *embic*, from which, by adding the Arabic *Al*, comes the term *Alembic*. The art of distillation, however, at that time, was in a very rude state; the operation being performed chiefly by separating the air, and more subtle part of tar, from the rest of the matter. This was done by putting the matter to be distilled into a vessel, the mouth of which was covered with a wet cloth; and by this the steams of ascending vapour were condensed, which were afterwards procured by wringing out the cloth. No other distillation, besides this kind, is mentioned by *Galen*, *Orbasius*, *Ælian*, or *Paulus Ægineta*.

5
Derivation
of the word
Alembic.

The precise time is not known when the three mineral acids were first discovered; though, as no mention is made of them by *Geber*, *Avicenna*, or *Roger Bacon*, it is probable that they were not known in the 12th century.

6
Original
method of
distilling.

tury. Raymond Lully gives some hints of his being acquainted with the marine acid; whence it is probable, that it was discovered towards the end of the 13th, or beginning of the 14th, century.

7
Pliny's account of the origin of glass-making.

Several chemical facts are related by Pliny, particularly the making of glass, which he ascribes to the following accident. "Some merchants in the Levant, who had nitre on board their ship, having occasion to land, lighted a fire on the sand in order to prepare their food. To support their vessels they took some of the lumps of nitre with which their ship was loaded; and the fire acting on these, melted part of them along with the sand, and thus formed the transparent substance called glass, to the great surprise of the beholders." But it is probable, that the art of glass-making was known long before; and it is by no means likely that it took its rise from such an accident.

8
Alchemy first mentioned by Firmicus Maternus.

The next traces we find of chemistry are to be extracted from the extravagant pursuits of the *Alchemists*, who imagined it possible to convert the baser metals into gold or silver. The first mention we find of this study is by Julius Firmicus Maternus, who lived in the beginning of the fourth century, and speaks of it as a well known pursuit in his time. *Aeneas Blausius*, who lived in the fifth century, likewise speaks of it; and *Suidas* explains the term by telling us, that it is the art of making gold and silver. He tells us, that *Dioclesian*, when persecuting the Christians, forbade all chemical operations, lest his subjects should discover the art of making gold, and thus be induced to rebel against him. He supposes also, that the *Argonautic expedition* was only an attempt to procure a skin or parchment, on which was written the *recipe* for making gold. It is a common practice, however, in some places where gold is washed down in small particles by brooks and rivulets from the mountains, to suspend in the water the skins of animals having wool or hair upon them, in order to detain the heavier particles which contain the gold; and this probably gave rise to the fable of the golden fleece. *Suidas*, however, who lived as late as the tenth century, deserves very little credit, especially as alchemy is not mentioned by any ancient author.—The Arabian physicians afford the most clear and distinct evidence concerning alchemy. *Avicenna*, who lived in the tenth century, is said by a disciple of his to have wrote upon alchemy; he mentions also rose-water, and some other chemical preparations; and in the 12th century we find physicians advised to cultivate an acquaintance with the chemists; and another of the Arabian writers say, that the method of preparing rose-water, &c. was then well known.—From this evidence of the existence of alchemy among the Arabians, with the prefatory article *Al*, to denote the greatness of the science, it has been conjectured, that the doctrine of the transmutation of metals first took its rise among the Arabians, and was introduced into Europe by means of the *Crusades*, and by the rapid conquests of the Arabians themselves in Europe as well as in Asia and Africa. Europe at that time had been in a state of the greatest barbarity from the incursions of the northern nations; but the Arabians contributed to revive some of the sciences, and introduced alchemy among the rest, which continued till the middle of the 17th century; at which time the

9
Origin of the fable of the Argonauts.

10
Alchemy first supposed to be derived from the Arabians.

extravagance of its professors rose to the greatest height.

Though the pretensions of the alchemists are now universally refuted, yet from some of the discoveries which have been made in chemistry, we are even yet in danger of giving some credit to the possibility of the process of transmutation. When we consider that the metals are bodies compounded of parts which we can take away and restore, and that they are closely allied to one another in their external appearance, we may be inclined to think favourably even of the projects of the alchemists. The very separation of the metals from their ores, the depriving them of their ductility and malleability, and the restoration of these properties to them at pleasure, will appear very surprising to those who are unacquainted with chemistry. There are also processes of the more difficult kind, by which quicksilver may be produced from metals that are commonly solid, as from lead. Some of these we find in *Boerhaave*, *Boyle*, &c. authors of the greatest credit, who both speak of the operation and product as realities of which they were convinced by their own experience. These have been urged, not without some plausibility, in favour of the transmutation of the imperfect metals into gold; and hence the delusions of alchemy were not confined to the vain, the ignorant, and the ambitious part of mankind; but many ingenious and learned men, who took pleasure in the study of nature, have been seduced into this unhappy pursuit. This happened chiefly in Germany, where the variety of mines naturally turned the thoughts of chemists principally towards the metals, though the numerous failures of those who had attempted this art ought to have taught them better.

11
No credit due to the doctrine of transmutation.

12
Quicksilver produced from lead.

About the beginning of the 16th century, the pretenders to alchemy were very numerous, and a multitude of knaves, who had beggared themselves in the attempt, now went about to ensnare others, performing legerdemain tricks, and causing people believe that they could actually make gold and silver. A number of the tricks they made use of are to be met with in *Lemery*. Many books, with the same design of imposing upon mankind, were written upon the subject of alchemy. They assumed fictitious names of the greatest antiquity, and contained rules for preparing the philosopher's stone; a small quantity of which thrown into a base metal should convert the whole into gold. They are wrote in a mysterious style, without any distinct meaning; and though sometimes processes are clearly enough described, they are found to be false and deceitful upon trial, the products not answering the pretensions of the authors. Their excuse was, that it was vain to expect plain accounts of these matters, or that the books on these subjects should be written distinctly and clearly; that the value of gold was in proportion to its scarcity, and that it might be employed to bad purposes: they wrote only for the laborious and judicious chemists, who would understand them provided they made themselves acquainted with the metals by study and experience. But in fact, no distinct meaning has ever been obtained, and the books have only served to delude and betray a great number of others into the loss of their *lives*.

But though the alchemists failed in the execution of their

13
Chemistry
derived
some ad-
vantages
from the
labours of
the alche-
mists.

their grand project, we must still own ourselves indebted to them for many discoveries brought to light during the time they vainly spent their labour in the expectation of making gold. Some of these are the methods of preparing spirit of wine, aquafortis, volatile alkali, vitriolic acid, and gun-powder. Medicine too was indebted to them for several valuable remedies; whence also it appears that many, who had wasted their time in the vain pursuit of the philosopher's stone, thought of trying some of their most elaborate preparations in the cure of diseases; and meeting with some success, they presumed that diseases were only to be cured by the assistance of chemistry; and that the most elaborate of all its preparations, the philosopher's stone, would cure all diseases. Some cures they performed did indeed awaken the attention of physicians; and they introduced the use of opium, which had formerly been accounted poisonous. They succeeded also in the cure of the venereal disease, which had lately made its appearance, and baffled the regular physicians; but the chemists, by giving mercury, put a stop to its ravages, and thus introduced this valuable article into the materia medica.

14
Account
of Paracel-
sus.

The most famous of the chemical professors was Paracelsus, well known for his arrogance, absurdity, and profligacy. He was bred to the study of medicine; but becoming acquainted with the alchemists, travelled about in the character of a physician, and was at great pains to collect powerful medicines from all quarters. These he used with great freedom and boldness. His success in some cases operated so upon the natural arrogance and self-sufficiency of his disposition, that he formed a design of overturning the whole system of medicine, and supplying a new one from chemistry: and indeed he found but very weak adversaries in the subtle theories of Galen with the refinements of the Arabian physicians, which only prevailed in his time; and he no doubt had some share in banishing that veneration which had been so long entertained for these celebrated personages.

15
History of
chemistry
since the
time of
Paracelsus.

16
The science
studied by
Lord Ver-
ulam;

From the time of Paracelsus, chemistry began everywhere to assume a new face. In our own country, Lord Verulam amused himself at his leisure hours with forming plans for promoting the sciences in general, especially those which related to the study of nature. He soon found that chemistry might turn out one of the most useful and comprehensive branches of natural philosophy, and pointed out the means of its improvement. A number of experiments were proposed by him; but he observed, that the views of chemists were as yet only adapted to explain their particular operations on metals; and he observed, that, instead of the abstruse and barren philosophy of the times, it was necessary to make a very large collection of facts, and to compare them with each other very maturely and cautiously, in order to discover the common causes and circumstances of connection upon which they all depend. He did not, however, make any considerable discoveries, and his works are tedious and disagreeable to the reader.

17
And by Mr
Boyle.

A superior genius to Lord Verulam was Mr Boyle, who was born the very day that the former died. His circumstances were opulent, his manners agreeable; he was endowed by nature with a goodness of heart; and his inclination led him entirely to the study of nature,

Nº 70.

which he was best pleased with cultivating in the way of experiment. He considered the weight, spring, and qualities of the air; and wrote on hydrostatics and other subjects; and was possessed of that happy penetration and ingenuity so well suited to the making of experiments in philosophy, which serves to deduce the most useful truths from the most simple and seemingly insignificant facts. As chemistry was his favourite science, he spared no pains to procure from chemists of greatest note the knowledge of curious experiments, and entertained a number of operators constantly about him. His discoveries are related in an easy style; and though rather copious, suited to the taste of the times in which he lived, and free from that absurd and mysterious air which formerly prevailed in chemical writings: nor does he betray a design of concealing any thing except some particulars which were communicated to him under the notion of secrecy, or the knowledge of which might do more harm than good. It is objected indeed, that he betrays a good deal of credulity with regard to facts which are given on the faith of others, and which may seem incredible; but this proceeded from his candour, and his being little disposed to suspect others. He showed the necessary connection between philosophy and the arts; and said, that by attending the shop of a workman, he learned more philosophy than he had done in the schools for a long time. Thus his writings showed an universal taste for the study of nature, which had now made some advances in the other parts of the world.

Agricola is one of the first and best authors on the subject of metallurgy. Being born in a village in Mis-
nia, a country abounding in mines and metallurgic
works, he described them exactly and copiously. He
was a physician, and cotemporary with Paracelsus, but
of a character very different. His writings are clear
and instructive, as those of Paracelsus are obscure and
useless. Lazarus Erker, Schinder, Schlutter, Henkel,
&c. have also written on metallurgy, and described
the art of assaying metals. Anthony Neri, Dr Mer-
ret, and the famous Kunkel (who discovered the phos-
phorus of urine), have described very fully the arts of
making glass, enamels, imitations of precious stones,
&c.: but their writings, as well as those of succeeding
chemists, are not free from the illusions of alchemy; so
true it is, that an obstinate and inveterate malady ne-
ver disappears at once, without leaving traces behind.
In a short time, however, the alchemical phrenzy was
attacked by many powerful antagonists, who contri-
buted to rescue the science of chemistry from an evil
which at once disgraced it and retarded its progress.
Among these, the most distinguished are Kircher a Je-
suit, and Conringius a physician, who wrote with much
success and reputation.

About the year 1650 the Royal Society was form-
ed by a number of gentlemen who were unwilling to
engage in the civil wars; and being struck with the
extensive views of Lord Verulam and Mr Boyle, con-
tributed to the expence of costly experiments. This
example appeared so noble, and the design so good,
that it has been followed by all the civilized states of
Europe, and has met with the protection of their re-
spective sovereigns; and from these chemistry has re-
ceived considerable improvements. In France, Geof-
froy, Lemery, Reaumur, &c. came to be distinguish-
ed;

18
Chemistry
emerges
from its ob-
scurity.

19
Royal So-
ciety how
founded.

ed; and in Germany Margraaf, Pott, and others, have made a considerable figure in those societies. Kunkel, Begar, Stahl, and Hoffman, &c. have done great service to society, by introducing new arts, and the numerous improvements they have made.

20
Of the improvements made by different nations in chemistry.

The chemists who have made a figure in Germany and France are more in number than those whom our island has produced. In France, the society was encouraged by the sovereign; and in it they have divested themselves of that mysterious air which was affected in former ages. In Germany, the richness of the country, and the great variety of mines, by turning the attention of chemists to the metals, have given that alchymistical air to their writings which we observe in them. The number of those who have applied them-

selves to chemistry is very small in England, owing to the great improvements made by Sir Isaac Newton in the sciences of astronomy and optics; which, by turning the general attention that way, has occasioned what may be called a neglect of chemistry. But if their number be inconsiderable, they are by no means inferior in merit and fame. The name of Boyle has always been held in the highest esteem, as well as that of Hales, for the analysis he has made of the air. Sir Isaac Newton alone has done more to the establishing a rational chemical theory than ever was done before. Of late, the taste for the study has become more general, and many useful books have appeared; so that it is to be hoped we shall soon excel in this branch of science, as we have done in all the rest.

PART I. THEORY OF CHEMISTRY.

21
Perfect Theory, what.

ACCORDING to the definition we have given of this science, the theory of it ought to consist in a thorough knowledge of all the phenomena which result from every possible combination of its objects with one another, or from exposing them in all possible ways to those substances which chemists have found to be the most active in producing a change. So various, however, and so widely extended are the objects of chemistry (comprehending all terrestrial bodies whatever), that a knowledge of this kind is utterly unattainable by man. The utmost that can be done in this case is, to give some account of the phenomena which accompany the mixtures of particular substances, or the appearances they put on when exposed to heat; and these have been already so well ascertained, that they may now be laid down as rules, whereby we may, with a good deal of certainty, judge of the event of our experiments, even before they are made.

22
Objects of Chemistry, what.

Here we must observe, that though the objects of chemistry are as various as there are different substances in the whole system of nature, yet they cannot all be examined with equal ease. Some of these substances act upon others with great violence; and the greater their activity, the more difficultly are they themselves subjected to a chemical examination. Thus, fire, which is the most active body in nature, is so little the subject of examination, that it hath hitherto baffled the ingenuity of the greatest philosophers to understand its composition. This substance, therefore, though it be the principal if not the only agent in chemistry, is not properly an object of it, because it cannot be made a subject of any chemical operation.

23
Supposition of elements the origin of alchemy.

It hath been customary to consider all bodies as composed of certain permanent and unchangeable parts called *elements*; and that the end of chemistry was to resolve bodies into these elements, and to recompose them again by a proper mixture of the elements when so separated. Upon this supposition the alchemists went; who, supposing that all bodies were composed of salt, sulphur, and mercury, endeavoured to find out the proportions in which these existed in gold, and then to form that metal by combining them in a similar manner. Had they taken care to ascertain the real existence of their elements, and, by mixing them together, composed any one metal whatever, though

but a grain of lead, the least valuable of them all; their pretensions would have been very rational and well founded; but as they never ascertained the existence of such elementary bodies, it is no wonder that their labours were never attended with success.

Another set of elements which were as generally received, and indeed continue to be so in some measure to this day, are fire, air, earth, and water.— This doctrine of elements was strenuously opposed by Mr Boyle; who endeavoured to prove, that fire was not an element *per se*, but generated merely from the motion of the particles of terrestrial bodies among one another; that air was generally produced from the substance of solid bodies; and that water, by a great number of distillations, was converted into earth. His arguments, however, concerning fire were not at all conclusive; nor does the expulsion of air from fixed bodies prove that any of their solid parts were employed in the composition of that air; as later discoveries have shown that air may be absorbed from the external atmosphere, and fixed in a great number of solid substances. His assertion concerning water deserves much consideration, and the experiment is well worth repeating; but it does not appear that he, or any other person, ought to have relied upon the experiment which was intended to prove this transmutation. The fact was this. Having designed to try the possibility of reducing water to earth by repeated distillations, he distilled an ounce of water three times over himself, and found a small quantity of earth always remaining. He then gave it to another, who distilled it 197 times. The amount of earth from the whole distillations was six drams, or $\frac{3}{4}$ ths of the quantity of water employed; and this earth was fixed, white, and insoluble in water.— Here it is evident, that great suspicions must lie against the fidelity of the unknown operator, who no doubt would be wearied out with such a number of distillations. The affair might appear trivial to him; and as he would perhaps know to which side Mr Boyle's opinion inclined, he might favour it, by mixing some white earth with the water. Had the experiment been tried by Mr Boyle's own hand, his known character would have put the matter beyond a doubt.

24
Mr Boyle's opinion.

The decomposition of water, however, in another way, by the combination of one part of it with the

phlogistic, and another with the earthy part of a metal, is now well ascertained, and the experiments which led to the discovery are treated of under the articles AEROLOGY and WATER.

25
Existence of
elements
disputed.

Even the existence of earth as an element appears as dubious as that of the others; for it is certain that there is no species of earth whatever, from which we can produce two dissimilar bodies, by adding their other component parts.—Thus, the earth of alum has all the characters of simplicity which we can desire in any terrestrial substance. It is white, insipid, inodorous, and perfectly fixed in the fire; nevertheless, it seems to be only an element of that particular body called *alum*; for though *alum* is composed of a pure earth and vitriolic acid joined together, and Epsom salt and selenite are both composed of a pure earth combined with the same acid; yet by adding oil of vitriol to the earth of alum, in any possible way, we shall never be able to form either Epsom salt or selenite. In like manner, though all the imperfect metals are composed of inflammable matter joined with an earthy basis; yet by adding to earth of alum any proportion we please of inflammable matter, we shall never produce a metal; and what is still more mortifying, we can never make the earthy basis of one metallic substance produce any other metal than that which it originally composed.

26
Elements
necessarily
invisible.

A little consideration upon the subject of elements will convince us, not only that no such bodies have ever yet been discovered, but that they never will; and for this plain reason, that they must be in their own nature invisible.—The component parts of any substance may with propriety enough be called the elements of that substance, as long as we propose carrying the decomposition no farther; but these elements have not the least property resembling any substance which they compose. Thus, it is found that the compound salt called *sal ammoniac*, is formed by the union of an acid and an alkali: we may therefore properly enough call these two the elements of *sal ammoniac*; but, taken separately, they have not the least resemblance to the compound, which is formed out of them. Both the acid and alkali are by themselves so volatile as to be capable of dissipation into an invisible vapour by the heat of one's hand; whereas, when joined together, they are so fixed as almost to endure a red heat without going off. If, again, we were to seek for the elements of the acid and alkali, we must not expect to find them have any properties resembling either an acid or an alkali, but others quite different. Any common element of all bodies must therefore be a substance which has no property similar to any other in the whole system of nature, and consequently must be imperceptible.

27
Supposition
concerning
phlogiston.

To the above-mentioned four elements, viz. fire, air, earth, and water, a kind of *fifth* element has generally been added, but not usually distinguished by that name, though it has apparently an equal, if not a greater, right to the title of an *element* than any of the others. This substance is called the *phlogiston*, or inflammable principle; on which the ignition of all bodies depends. The existence of this element was first asserted by Stahl, and from him the opinion has been derived to other chemists: but of late a new doctrine was broached by M. Lavoisier, who denies the exist-

ence of phlogiston altogether. Though none of these substances therefore are properly the objects of chemistry, yet as they have so much ingrossed the attention of modern chemists, we shall here give an account of the most remarkable theories that have appeared concerning them.

Of the
Element
of Fire.

SECT. I. Of the Element of Fire.

THE opinions concerning the element of fire may be divided into two general classes; the one considering it as an effect, the other as a cause. The former is maintained by Lord Bacon, Mr Boyle, and Sir Isaac Newton; whose respectable names for a long time gave such a sanction to this theory, that it was generally looked upon as an established truth. Some learned men, however, among whom was the great Dr Boerhaave, always dissented, and insisted that fire was a fluid universally diffused, and equally present in the frozen regions of Nova Zembla as in a glass-house furnace, only that in the latter its motion made it conspicuous; and by setting it in motion in the coldest parts of the world, its previous existence there would be equally demonstrable as in the furnace above-mentioned.

28
Two gene-
ral theories
of heat.

Lord Bacon defines heat, which he uses as a synonymous term with fire, to be an expansive undulatory motion in the particles of a body, whereby they tend with some rapidity towards the circumference, and also a little upwards. Hence, if in any natural body you can excite a motion whereby it shall expand or dilate itself, and can repress and direct this motion upon itself in such a manner that the motion shall not proceed uniformly, but obtain in some parts and be checked in others, you will generate heat or fire.

29
Lord Ba-
con's defi-
nition of
heat.

The same opinion is supported by Mr Boyle in the following manner: "The production of heat discovers nothing, either in the agent or patient, but motion, and its natural effects. When a smith briskly hammers a small piece of iron, the metal thereby becomes exceedingly hot: yet there is nothing to make it so, except the motion of the hammer impressing a vehement and variously determined agitation on the small parts of the iron; which, being a cold body before, grows hot by that superinduced motion of its small parts: first, in a more loose acceptation of the word, with regard to some other bodies, in comparison of which it was cold before; then sensibly hot, because the motion in the parts of the iron is greater than that in the parts of our fingers; at the same time that the hammer and anvil, by which the percussion is communicated, may, on account of their magnitude, remain cold. It is not necessary, therefore, that a body should itself be hot in order to communicate heat to another."

30
Mr Boyle's
opinion.

The arguments made use of by Sir Isaac Newton are not intended positively to establish any kind of theory relating to fire, but are to be found in a conjecture, published at the end of his *Treatise on Optics*, concerning the nature of the sun and stars. "Large bodies (he observes) preserve their heat the longest, their parts heating one another; and why may not great, dense, and fixed bodies, when heated beyond a certain degree, emit light so copiously, as, by the emission and reaction of it, and the reflections and refractions within the pores, to grow continually hotter, till they arrive at such a period of heat as is that of the sun? Their parts

31
Sentiments
of Sir Isaac
Newton.

Of the
Element
of Fire.

parts may be further preserved from fuming away, not only by their fixity, but by the vast weight and density of the atmosphere incumbent on them, strongly compressing them, and condensing the vapours exhaled from them. Thus we see, that warm water, in an exhausted receiver, shall boil as vehemently as the hottest water exposed to the air; the weight of the incumbent atmosphere in this latter case keeping down the vapours, and hindering the ebullition till it has received its utmost degree of heat. Thus also a mixture of tin and lead, put on a red hot iron *in vacuo*, emits a fume and flame; but the same mixture in the open air, by reason of the incumbent atmosphere, does not emit the least sensible flame." In consequence of these experiments, Sir Isaac conjectures, that there is no essential distinction betwixt fire and gross bodies; but that they may be converted into one another. "Fire (he says) is a body heated so hot as to emit light copiously; for what (says he) is a red hot iron but fire?"

32
Fire now

mer.

35
General
account of
Dr Black's
and Dr Ir-
vine's the-
ory.

The hypotheses of these great men produced long and violent disputes, which were never decisively settled: The discoveries in electricity, however, furnished such additional strength to the followers of Dr Boerhaave, that fire is now believed to be an element and fluid distinct from all others, by at least as many as espouse the contrary system; but the question is not decided, Whether the fire itself is to be considered as the agent? or, Whether its action is to be derived from the principles of attraction and repulsion, the natural agents supposed to influence other material substances? This has produced two other systems of a kind of mixed nature, in which heat or fire is considered as a substance distinct from all others, but which acts in other bodies according to its quantity. These systems have been promulgated by Dr Black of Edinburgh and Dr Irvine of Glasgow. They differ from the opinions of Mr Boyle, Lord Bacon, and Sir Isaac Newton, in supposing heat to be a fluid distinct from all other material substances; and they also differ from the hypotheses of Dr Boerhaave, Lemery, and others, in supposing different terrestrial substances to be hot according to the quantity of fluid contained, and not according to the force with which it moves in them.

Dr Black is of opinion that *heat*, which he seems to make synonymous with fire, exists in two different states; in one of which it affects our senses and the thermometer, in the other it does not. The former therefore he calls *sensible* heat, the latter *latent* heat. On these principles he gives the only satisfactory explanation of the phenomena of evaporation and fluidity that has yet appeared, as shall afterwards be more fully explained. At present we shall only observe, that, according to the theory of Dr Black, heat or fire itself seems to be the agent; but, according to that of Dr Irvine, as far as we can gather it from the treatises of Dr Crawford and others, the principles of attraction and repulsion are the agents by which heat, as well as other bodies, is influenced. Thus, on the principles of Dr Black, we say, that water is converted into vapour by a quantity of heat entering into it in a *latent* state, and thereby rendering it specifically lighter than the atmosphere: according to the principles of Dr Irvine, we say, that water is converted into vapour by having its capacity for attracting heat from the

atmosphere increased. So that, according to the former, the absorption of heat is the *cause*; according to the latter, the *effect*, of its conversion into vapour.

Dr Crawford, in his Treatise on Heat, published in 1788, informs us, that *heat*, in the philosophical sense of the word, has been used to express what is frequently called the *element of fire*, in the abstract, without regard to the peculiar effects which it may produce in relation to other bodies. This, with Dr Irvine, he calls *absolute* heat; and the external cause, as having a relation to the effects it produces, he calls *relative* heat. "From this view of the matter (says he), it appears, that *absolute* heat expresses, in the abstract, that *power* or *element* which, when it is present to a *certain* degree, excites in all animals the sensation of heat; and *relative* heat expresses the same power, considered as having a relation to the effects by which it is known and measured.

"The effects by which heat is known and measured are three; and therefore relative heat may admit of three subdivisions. 1. This principle is known by the peculiar sensations which it excites in animals. Considered as exciting those sensations, it is called *sensible* heat. 2. It is known by the effect which it produces upon an instrument that has been employed to measure it, termed a *thermometer*. This is called the *temperature of heat in bodies*. 3. It has been found by experiment, that in bodies of different kinds the quantities of absolute heat may be unequal, though the temperatures and weights be the same. When the principle of heat is considered relatively to the whole quantity of it contained in bodies of different kinds, but which have equal weights and temperatures, I shall term it *comparative* heat. If, for example, the temperatures and weights being the same, the whole quantity of heat in water be four times as great as that of antimony, the comparative heats of these substances are said to be as four to one."

In order to have a proper conception of what is meant by a difference in absolute heat, when the temperatures are the same, it will be necessary to relate some experiments, by which Dr Black was first led to the discovery of latent heat. He observes, that when two equal masses of the same matter, heated to different degrees, are mixed together, the heat of the mixture ought to be an arithmetical mean betwixt the two extremes. This, however, only takes place on mixing hot and cold water together; but if instead of cold water we take ice, the case is remarkably different. Here the temperature of the mixture is much below the arithmetical mean, and a quantity of heat is apparently lost. Now we know that the temperature of ice newly frozen is generally 32 degrees of Fahrenheit; supposing therefore the temperature of the water which dissolves it to be 120°, the arithmetical mean is 71; but if the mixture indicates a temperature only of 60°, then we must suppose that the ice contained 11° of heat less than was indicated by the thermometer; and consequently, that water at 32° contains 11° more of absolute heat than ice at 32°.

The same thing is made still more evident from the condensation of vapour. The fluid of water is not capable of sustaining a great degree of heat; and 212° of Fahrenheit is the utmost it can be made to bear, without an extraordinary degree of pressure, as in Pa-

pin's digester, or the admixture of saline substances: the temperature of the steam emitted by it therefore never can exceed 212° , except in the cases just mentioned; and it is often capable of bearing a great degree of cold without being condensed. When the condensation takes place at last, however, a very considerable degree of heat is always produced; and Dr Black has shown, that, in the condensation of steam by the refrigeratory of a common still, as much heat is communicated to the water in the refrigeratory as would be sufficient to make the water which comes over as hot as red hot-iron, were it all to exist in a sensible state. His method of making the calculation is very easy. For, supposing the refrigeratory to contain 100 pounds of water, and that one pound has been distilled; if the water in the refrigeratory has received 10 degrees of heat, we know that the distilled pound has parted with 1000. If in passing through the worm of the refrigeratory, it has been reduced to the temperature of 50° of Fahrenheit, having been at 212° when it entered it, then it has lost only 162° of sensible heat; all the rest communicated to the water of the refrigeratory amounting to more than 800° , having been contained in a latent state, and such as could not then affect the thermometer. This experiment was tried by Mr Watt in a manner still more striking, by a distillation of water *in vacuo*. Thus the steam, freed from the pressure of the atmosphere, could not conceive such a degree of sensible heat as in the common method of distilling. It came over therefore with a very gentle warmth, scarce more than what the hand could bear; nevertheless it had absorbed as much heat as though the distillation had been performed in the common way; for the refrigeratory had 1000 degrees of heat communicated to it.

The difference of absolute heat is likewise perceptible betwixt any two bodies of different density, water and mercury for instance: and in comparing these, it will always be found that the thinnest fluids contain the greatest quantity of absolute heat; as water more than mercury, spirit of wine more than water, ether more than spirit of wine, and air more than any of them. Dr Black having brought equal bulks of mercury and water, the former to a temperature of 50 degrees higher than the latter, found that, on mixture, there was a gain of only 20 degrees above the original; but on reversing the experiment, and heating the water 50 degrees above the mercury, there was a gain of 30 degrees on the whole. "Hence (says Dr Cleghorn in his thesis *de Igne*) it appears, that the quantity of heat in water is to that in mercury, when both are of equal temperatures, as 3 to 2." Dr Crawford, however, tells us, that "the same quantity of heat which raises a pound of water one degree, will raise a pound of mercury 28 degrees; whence it follows, that the comparative heat of water is to that of mercury as 28 to 1: and consequently, the alterations which are produced in the temperatures of bodies by given quantities of absolute heat, may properly be applied as a measure of their comparative heats; the alterations of temperature and the comparative heats being reciprocally proportional to one another.

"Sensible heat (continues Dr Crawford) depends partly on the state of the temperature, and partly on that of

the organ of feeling; and therefore if a variation be produced in the latter, the sensible heat will be different, though the temperature continue the same. Thus water at the temperature of 62° of Fahrenheit appears cold to a warm hand immersed in it; but on the contrary, that fluid will appear warm if a hand be applied to it which has a lower degree of heat than 62° . For this reason, the thermometer is a much more accurate measure of heat than the senses of animals. As long, however, as the organs remain unchanged, the sensible heat is in proportion to the temperature; and therefore those terms have generally been considered as synonymous. On this subject Dr Reid observes, that until the ratio between one temperature and another be ascertained by experiment and induction, we ought to consider temperature as a measure which admits of degrees, but not of ratios; and consequently ought not to conclude, that the temperature of one body is double or triple to that of another, unless the ratio of different temperatures were determined. Nor ought we to use the expressions of a *double* or *triple* temperature, these being expressions which convey no distinct meaning until the ratio of different temperatures be determined."

In making experiments on the comparative quantities of heat in different bodies, our author chooses rather to use equal *weights* than equal *bulks* of the substances to be compared. Thus he found the comparative heat of water to be to that of mercury as 28 to 1 by weight, and 2 to 1 by bulk; which differs very considerably from the conclusion of Dr Black, who makes it only as 3 to 2, as has been already mentioned.

From the differences observed in the quantities of absolute heat contained in different bodies, our author concludes, that "there must be certain essential differences in the nature of bodies; in consequence of which, *some* have the power of collecting and retaining that element in greater quantity than *others*." These different powers he calls the *capacities* for containing heat. Thus, if we find by experiment that a pound of water contains four times as much absolute heat as diaphoretic antimony, when at the same temperature, the capacity of water for containing heat is said to be to that of antimony as 4 to 1.

"The temperature, the capacity for containing heat, and the absolute heat contained, may be distinguished from each other in the following manner:

"The capacity for containing heat, and the absolute heat contained, are distinguished as a force distinct from the subject upon which it operates. When we speak of the capacity, we mean a power inherent in the heated body; when we speak of the absolute heat, we mean an unknown principle which is retained in the body by the operation of this power; and when we speak of the temperature, we consider the unknown principle as producing certain effects upon the thermometer.

"The capacity for containing heat may continue unchanged, while the absolute heat is varied without end. If a pound of ice, for example, be supposed to retain its solid form, the quantity of its absolute heat will be altered by every increase or diminution of its sensible heat: but as long as its form continues the same, its capacity for receiving heat is not affected by

an alteration of temperature, and would remain unchanged though the body were wholly deprived of its heat."

54
Crawford's
opinion
concerning
heat in the
abstract.

In the course of his work, Dr Crawford observes, that "he has not entered into the inquiry which has been so much agitated among the English, the French, and the German philosophers, Whether heat be a *substance* or a *quality*? In some places indeed he has used expressions which seem to favour the former opinion; but his sole motive for adopting these was, because the language seemed to be more simple and natural, and more consonant to the facts which had been established by experiment. At the same time, he is persuaded that it would be a very difficult matter to reconcile many of the phenomena with the supposition that heat is a *quality*. It is not easy to conceive, upon this hypothesis, how heat can be absorbed in the processes of fusion, evaporation, combustion; how the quantity of heat in the air can be diminished, and that in the blood increased, by respiration, though no sensible heat or cold be produced.

"Whereas, if we adopt the opinion that heat is a distinct substance, or an element *sui generis*, the phenomena will be found to admit of a simple and obvious interpretation.

55
Fire con-
tained in
bodies part-
ly by its
attraction
to them,
and partly
the pressure
of the ex-
ternal fluid.

"Fire will be considered as a principle; which is distributed in various proportions throughout the different kingdoms of nature. The mode of its union with bodies will resemble that particular species of union, wherein the elements are combined by the joint forces of pressure and attraction. Of this kind is the combination of fixed air and water; for fixed air is retained in water partly by its attraction for that fluid, and partly by the pressure of the external air; and if either of these forces be diminished, a portion of the fixed air escapes. In like manner, it may be conceived that elementary fire is retained in bodies, partly by its attraction to these bodies, and partly by the action of the surrounding heat; and in that case a portion of it will be disengaged, either by diminishing the attractive force, or by lessening the temperature of the circumambient medium. If, however, fire be a substance which is subject to the laws of attraction, the mode of its union with bodies seems to be different from that which takes place in chemical combination: for, in chemical combination, the elements acquire new properties, and either wholly or in part lose those by which they were formerly characterized. But we have no sufficient evidence for believing that fire, in consequence of its union with bodies, does, in any instance, lose its distinguishing properties."

56
Dr Berken-
hout's opi-
nion con-
cerning the
nature of
heat.

Dr Berkenhout, in his First Lines of the Theory and Practice of Philosophical Chemistry, informs us, that "heat, or the *matter of heat*, is by Scheele and Bergman substituted for fire, which they believe to be the action of heat when increased to a certain degree. The first of these celebrated chemists believed this *matter of heat* to be a compound of phlogiston and pure air. He was certainly mistaken. It seems more philosophical to consider heat as an *effect*, of which fire is the sole cause.

57
His divi-
sion of fire
into fixed
and vola-
tile.

"Heat I consider not as a distinct substance, but as an effect of fire, fixed or volatile; in both which states fire seems to exist in all bodies, solid and fluid. Fixed fire I believe to be a constituent part of all bodies,

and their specific heat to depend on the quantity of fixed fire in each. This fixed, this latent fire, cannot be separated from the other constituent parts of bodies but by their decomposition: it then becomes volatile and incoercible. If this hypothesis be true, fire exists, in all natural bodies that contain phlogiston, in three different states: 1. In that volatile state in which it perpetually fluctuates between one body and another. 2. Combined with an acid, probably in the form of fixed inflammable air or phlogiston. 3. Uncombined and fixed, as a constituent principle, determining the specific heat of bodies.

"Pure (or volatile) fire is distinguished by the following properties. 1. It is essentially fluid, invisible, and without weight. 2. It is the immediate cause of all fluidity. 3. It penetrates and pervades all bodies on the surface of the earth, and as far beneath the surface as hath hitherto been explored. Water hath never been found in a congealed state in the deepest mines. 4. It has a constant tendency to diffuse itself equally through all bodies, howsoever different in point of density. A marble slab, a plate of iron, a decanter of water, and a lady's muff, at the same distance from the fire, and other external circumstances, being equal, possess an equal degree of heat, which is precisely that of the atmosphere in which they stand. 5. It is perpetually in motion from one body to another, and from different parts of the same body, because external circumstances are continually varying. 6. In fluctuating from one body to another, it produces a constant vibration of their constituent parts; for all bodies expand and contract in proportion to the quantity of fire they contain. 7. Accumulated beyond a certain quantity, it effects the dissolution of bodies, by forcing their constituent parts beyond the sphere of mutual attraction, called the *attraction of cohesion*, which is the cause of solidity. Hence the sovereign agency of fire in chemical operations."

Dr Crawford, besides the opinions already quoted, tells us, that fire, in the vulgar acceptation of the word, expresses a certain degree of heat accompanied with light; and is particularly applied to that heat and light which are produced by the inflammation of combustible bodies. But as heat, when accumulated in a sufficient quantity, is constantly accompanied with light; or, in other words, as fire is always produced by the increase of heat, philosophers have generally considered these phenomena as proceeding from the same cause: and have therefore used the word *fire* to express that unknown principle, which, when it is present to a certain degree, excites the sensation of heat alone; but, when accumulated to a greater degree, renders itself obvious both to the sight and touch, or produces heat accompanied with light. In this sense, the element of fire signifies the same thing with *absolute heat*.

Having premised these general definitions and remarks, he gives the properties of heat in the following words:

"I. Heat has a constant tendency to diffuse itself over all bodies till they are brought to the same temperature. Thus it is found by the thermometer, that if two bodies of different temperatures are mixed together, or placed contiguous, the heat passes from the one to the other till their temperatures become equal; and

tendency
to diffuse
itself e-
venly over
bodies,
and

and that all inanimate bodies, when heated and placed in a cold medium, continually lose heat, till in process of time they are brought to the state of the surrounding medium.

"From this property of heat it follows, that the various classes of bodies throughout the earth, if they were not acted upon by external causes, would at length arrive at a common temperature when the heat would become quiescent; in like manner as the waters of the ocean, if not prevented by the winds and by the attractions of the sun and moon, would come to an equilibrium, and would remain in a state of rest. But as causes continually occur in nature to disturb the balance of heat as well as that of the waters of the ocean, those elements are kept in a constant fluctuation.

"II. Heat is contained in considerable quantities in all bodies when at the common temperature of the atmosphere.

"From the interesting experiments which were made on cold by Mr Wilson, we learn, that at Glasgow, in the winter of the year 1780, the thermometer on the surface of snow sunk 25 degrees below the beginning of Fahrenheit's scale.

"We are told by Dr Pallas, that in the deserts of Siberia, during a very intense frost, the mercury was found congealed in thermometers exposed to the atmosphere, and a quantity of that fluid in an open bowl placed in a similar situation, at the same time became solid. The decisive experiments of Mr Hutchins at Hudson's Bay prove, that the freezing point of mercury is very nearly 40° below the zero (or 0°) of Fahrenheit. From which it follows, that at the time of Dr Pallas's observation, the atmosphere in Siberia must have been cooled to minus 40. By a paper lately transmitted to the Royal Society we are informed, that the spirit-of-wine thermometer in the open air at Hudson's Bay fell to — 42 in the winter of 1785; and from the same communication we learn, that by a mixture of snow and vitriolic acid, the heat was so much diminished, that the spirit of wine sunk to — 80, which is 112 below the freezing point of water.

"Hence it is manifest, that heat is contained in considerable quantities in all bodies when at the common temperature of the atmosphere. It is plain, however, that the quantity inherent in each individual body is limited. This, I think, must be admitted, whatever be the hypothesis which we adopt concerning the nature of heat; whether we conceive it to be a force or power belonging to bodies, or an elementary principle contained in them. For those who consider heat as an element, will not suppose that an unlimited quantity of it can be contained in a finite body; and if heat be considered as a force or power, the supposition that finite bodies are actuated by forces or powers which are infinite is equally inadmissible.

"To place this in another light, we know that bodies are universally expanded by heat, excepting in a very few instances, which do not afford a just objection to the general fact; because, in those instances, by the action of heat a fluid is extricated that previously separated the particles from each other. Since, therefore, heat is found to expand bodies in the temperatures which fall within the reach of our observation, we may conclude that the same thing takes place in all temperatures."

Our author, by a set of very accurate and laborious experiments, determines that the expansions in mercury and some other fluids are proportionable to the quantities of heat applied; "from which (says he) it is manifest, that the quantities of heat in bodies are limited, because an infinite heat would produce an infinite expansion.

"It is manifest, that the number of degrees of sensible heat, as measured by the thermometer, and estimated from the beginning of the scale, must be the same in all bodies which have a common temperature; for by the first general fact it is proved, that heat has a constant tendency to diffuse itself uniformly over bodies till their temperatures become equal. From which it may be inferred, that if a quantity of heat were added to bodies absolutely cold, the same uniform diffusion would take place; and that if a thermometer, altogether deprived of its heat, were applied to such bodies, it would be equally expanded by them, the whole of the sensible heat which they had acquired being indicated by that expansion.

"III. If the parts of the same homogeneous substance have a common temperature, the quantity of absolute heat will be proportional to the bulk or quantity of matter. Thus the quantity of absolute heat in two pounds of water is double that which is contained in one pound when at the same temperature.

"IV. The dilatations and contractions of the fluid in the mercurial thermometer are nearly proportional to the quantities of absolute heat which are communicated to the same homogeneous bodies, or separated from them, as long as they retain the same form. Thus the quantity of heat required to raise a body four degrees in temperature by the mercurial thermometer, is nearly double that which is required to raise it two degrees, four times that required to raise it one degree, and so in proportion."

Thus we find, that Dr Black, Dr Irvine, Dr Crawford, and Dr Berkenhout, agree in speaking of fire or heat as a fluid substance distinct from all other bodies. Mr Kirwan, in his Treatise of Phlogiston, agrees in the same opinion. "Some (says he) have thought, that I should have included the matter of heat, or elementary fire, in the definition of inflammable air; but as fire is contained in all corporeal substances, to mention it is perfectly needless, except where bodies differ from each other in the quantity of it they contain." On the other hand, Mr Cavendish, Phil. Trans. lxxiv. p. 141. tells us, that "he thinks it more likely that there is no such thing as elementary heat;" but, as he gives no reason for this opinion, it seems probable that the greater part of philosophers either positively believe that heat is an elementary fluid distinct from all others, or find themselves obliged to adopt a language which necessarily implies it. The only difficulty which now remains therefore is, to affix a proper idea to the phrase *quantity of heat*, which we find universally made use of, without any thing to determine our opinions concerning it.

That we cannot speak of a *quantity* of fire or heat in the same sense as we speak of a quantity of water or any other fluid is evident, because we can take away the quantity of water which any substance contains, but cannot do so with heat. Nay, in many cases we are sure, that a substance very cold to the touch does

yet contain a very considerable quantity of heat. The vapour of water, for instance, may be made much colder than the usual temperature of the atmosphere without being condensed, when at the same time we are certain that it contains a great quantity of heat; and the same may be said of water, which, in the act of freezing, throws out a great quantity of heat without becoming colder; and in the act of melting absorbs as much without becoming warmer. It is not therefore by the mere presence or absence of this fluid that we can determine the real quantity of this fluid; nor does it appear that the word *quantity* can be at all accurately applied to the element itself, because we have no method of measuring it.

72
Dr Cleghorn's opinion.

Dr Cleghorn, in his inaugural dissertation *De Igne*, throws some light on this subject, by observing, that "the thermometer shows only the quantity of heat going out of a body, not that which is really contained in it:" and he also insists, that "we can neither assent to the opinion of Dr Boerhaave, who supposed that heat was distributed among bodies in proportion to their bulks; nor to the hypotheses of others, who imagined that they were heated in proportion to their densities." But in what proportion, then, are they heated; or how are we to measure the *quantity* which they really contain, seeing the thermometer informs us only of what they part with?

73
The latent heat of bodies cannot be measured.

As this point is by no means ascertained, we cannot form a direct idea concerning the absolute quantity of heat contained in any body; and therefore when we speak of quantities of this fluid, we must in fact, if we mean any thing, think of the sensible quantity flowing out of them; and though we should suppose the whole of this sensible heat to be removed, it would still be impossible for us to know how much remained in a latent state, and could not be dissipated. This difficulty will still appear the greater, if with Dr Cleghorn and others we suppose the fluid of heat to be subject to the laws of attraction and repulsion. This gentleman supposes, that the particles of heat (like the particles of electric fluid according to the Franklinian hypothesis) are repulsive of one another, but attracted by all other substances. "If any body (says he), heated beyond the common temperature of the air, is exposed to it, the heat flows out from it into the atmosphere, and diffuses itself equally all around till the air becomes of the same temperature with itself. The same happens to bodies suspended *in vacuo*. Hence it is justly concluded, that there exists between the particles of heat a repulsive power, by which they mutually recede from each other. Notwithstanding this repulsive power, however, the quantities of heat contained in different substances, even of the same temperature, are found to be altogether different; and from Dr Black's experiments it now appears, that the quantity of heat is scarce ever the same in any two different bodies: and hence we may conclude, that terrestrial bodies have a power of attracting heat, and that this power is different in different substances.—From these principles it evidently follows, that heat is distributed among bodies directly in proportion to their attracting powers, and inversely according to the repulsive power between the particles of heat themselves. Such is the distribution of heat among bodies in the neighbourhood of each other, and which is called the *equilibrium of heat*, be-

74
Dr Cleghorn's hypothesis concerning fire.

75
Equilibrium of heat defined.

cause the thermometer shows no difference of temperature among them. For seeing the heat is distributed according to the attracting power of each, the thermometer having also a proper attraction of its own, can show no difference in the attracting power of each; for which reason all bodies in the neighbourhood of each other are soon reduced to the same temperature."

If we assent to Dr Cleghorn's hypothesis, the quantity of heat contained in any substance depends, in the first place, on the attracting power of that substance, which is altogether unknown; and, in the second place, on the repulsive powers of the particles of heat themselves, which are equally unknown. To determine the *quantity*, therefore, must be impossible. Neither will the mixture of two different fluids, as in Dr Black's experiments, assist us in the least; for though water, heated more than mercury, communicates a greater heat to that fluid than the latter does to water; this only shows that water more readily parts with some part of the heat it contains than mercury does, but has not the least tendency to discover the quantity contained in either.

Dr Crawford, as we have already seen, calls the *degree*, or, if we may vary the phrase, the *quantity of power or element* (fluid, if we may substitute a synonymous word) existing or present in any body, its *absolute heat*; and lays down a rule for determining the proportional quantities of heat in different bodies. "It will appear (says he) from the experiments afterwards recited, that if a pound of water and a pound of diaphoretic antimony have a common temperature, the quantity of absolute heat contained in the former is nearly four times that contained in the latter."—The manner in which he illustrates this is as follows.

"If four pounds of diaphoretic antimony at 20 be mixed with one pound of ice at 32, the temperature will be nearly 26: the ice will be cooled six degrees, and the antimony heated six. If we reverse the experiment, the effect will be the same. That is, if we take six degrees of heat from four pounds of antimony, and add it to a pound of ice, the latter will be heated six degrees. The same quantity of heat, therefore, which raises a pound of ice six degrees, will raise four pounds of antimony six degrees.

"If this experiment be made at different temperatures, we shall have a similar result. If, for example, the antimony at 15, or at any given degree below the freezing point, be mixed with the ice at 32, the heat of the mixture will be the arithmetical mean between that of the warmer and colder substance. And since the capacities of bodies are permanent as long as they retain the same form, we infer, that the result would be the same if the antimony were deprived of all its heat, and were mixed with the ice at 32. But it is evident, that in this case the ice would communicate to the antimony the half of its absolute heat. For if 200 below frost be conceived to be the point of total privation, the antimony will be wholly deprived of its heat when cooled to 200 degrees below 32, and the heat contained in the ice when at 32 will be 200 degrees. If we now suppose them to be mixed together, the temperature of the mixture will be half the excess of the hotter above the colder, or the ice will be

Of the
Element
of Fire.

76
The quantity of heat cannot be determined by this hypothesis.

77
Dr Crawford's method of determining the proportional quantities of heat.

he cooled 100 degrees and the antimony heated 100. The one half of the heat, therefore, which was contained in the ice previous to the mixture will be communicated to the antimony; from which it is manifest, that after the mixture the ice and antimony must contain equal quantities of absolute heat.

"To place this in another light, it has been proved, that the same quantity of heat which raises a pound of ice six degrees will raise four pounds of antimony six degrees. And as the capacities of bodies, while they retain the same form, are not altered by a change of temperature; it follows, that the same quantity of heat which raises the ice 200 degrees, or any given number of degrees, will raise the antimony an equal number of degrees.

"A pound of ice, therefore, and four pounds of antimony, when at the same temperature, contain equal quantities of absolute heat. But it appears from the third general fact (n^o 67.), that four pounds of antimony contain four times as much absolute heat as one pound of antimony; and hence the quantity of absolute heat in a pound of ice is to that in a pound of antimony as four to one."

78
His method
insufficient.

From this quotation it is evident, that, notwithstanding all the distinctions which Dr Crawford has laid down betwixt absolute heat and temperature, it is only the *quantity* of the latter that can be measured; and all that we can say concerning the matter is, that when certain bodies are mixed together, some of them part with a greater quantity of heat than others; but how much they *contain* must remain for ever unknown, unless we can fall on some method of measuring the quantity of heat as we do that of any other fluid.

79
Nicholson's
account of
the theories
of heat.

Mr Nicolson, who has collected the principal opinions on the subject of heat, seems undetermined whether to believe the doctrine of Boyle or of Boerhaave on the subject. "There are two opinions (says he) concerning heat. According to one opinion, heat consists in a vibratory motion of the parts of bodies among each other, whose greater or less intensity occasions the increase or diminution of temperature. According to the other opinion, heat is a subtle fluid that easily pervades the pores of all bodies, causing them to expand by means of its elasticity or otherwise. Each of these opinions is attended with its peculiar difficulties. The phenomena of heat may be accounted for by either of them, provided certain suppositions be allowed to each respectively; but the want of proof of the truth of such suppositions renders it very difficult, if not impossible, to decide as yet whether heat consists merely in motion or in some peculiar matter. The word *quantity*, applied to heat, will therefore denote either motion or matter, according to the opinion made use of, and may be used indefinitely without determining which.

80
Advantages of the
doctrine
that heat
is caused
by vibra-
tion.

"The chief advantage which the opinion that heat is caused by mere vibration possesses, is its great simplicity. It is highly probable, that all heated bodies have an intestine motion, or vibration of their parts; and it is certain that percussion, friction, and other methods of agitating the minute parts of bodies, will likewise increase their temperature. Why, then, it is demanded, should we multiply causes, by supposing the existence of an unknown fluid, when the mere vi-

N^o 70.

bration of parts which is known to obtain may be applied to explain the phenomena?"

To this the reply is obvious, that the vibration of parts is an *effect*; for matter will not begin to move of itself: and if it is an effect, we must suppose a cause for it; which, though we should not call it a fluid, would be equally unknown and inexplicable with that whose existence is asserted by those who maintain that fire is a fluid *per se*. Dr Cleghorn, however, in the dissertation already quoted, asserts, that "heat is occasioned by a certain fluid, and not by motion alone, as some eminent writers have imagined: because, 1. Those who have adopted the hypothesis of motion could never even prove the existence of that motion for which they contended; and though it should be granted, the phenomena could not be explained by it. 2. If heat depended on motion, it would instantaneously pass through an elastic body; but we see that heat passes through bodies slowly like a fluid. 3. If heat depended on vibration, it ought to be communicated from a given vibration in proportion to the quantity of matter; which is found not to hold true in fact. On the other hand, there are numberless arguments in favour of the opinion that heat proceeds from elementary fire. 1. Mr Locke hath observed, that when we perceive a number of qualities always existing together, we may gather from thence that there really is some substance which produces these qualities. 2. The hypothesis of elementary fire is simple and agreeable to the phenomena. 3. From some experiments made by Sir Isaac Newton, it appears, that bodies acquire heat and cold *in vacuo*, until they become of the same temperature with the atmosphere; so that heat exists in the absence of all other matter, and is therefore a substance by itself."

But though these and other arguments seem clearly to establish the point that fire or heat is a distinct fluid, we are still involved in very great difficulties concerning its nature and properties. If it be supposed a fluid, it is impossible to assign any limits to its extent; and we must of necessity likewise suppose that it pervades the whole creation, and consequently constitutes an absolute plenum, contrary to a fundamental principle of the received system of natural philosophy. But if this is the case, it is vain to talk of its being absorbed, accumulated, collected, or attracted by different bodies, since it is already present in all points of space; and we can conceive of terrestrial bodies no otherwise than as sponges thrown into the ocean, each of which will be as full of fluid as it can hold. The different capacities will then be similar to the differences between bits of wood, sponge, porous stones, &c. for containing water; all of which depend entirely on the structure of the bodies themselves, and which, unless we could separate the water by pressure, or by evaporation, would be for ever unknown. Supposing it were impossible to collect this water in the manner we speak of, we could only judge of the quantity they contained by the degree to which they swelled by being immersed in it. It is easy to see, however, that such a method of judging would be very inadequate to the purpose, as substances might contain internal cavities or pores in which water could lodge without augmenting the external bulk. This would suggest another method of judging of the quantity, namely, the specific gravity;

Element
of Fire.

vity; and we might reasonably suppose, that substances of the greatest specific gravity would contain the smallest quantity of water, though still we could by no means determine what quantity they did contain, unless we could lay hold of the element itself.

This seems to be very much the case with elementary fire, if we suppose it to be a fluid *per se*. We judge of its presence by the degree of expansion which one heated body communicates to another: but this is only similar to the calculation of the quantity of moisture a sponge or any other body contains, by what it communicates to wood when it comes into contact with it; which never could be supposed to carry the least pretensions to accuracy, though we should ascertain it with all imaginable exactness. It is likewise probable that the most dense bodies contain the smallest quantity of fire, as they generally communicate less when heated to an equal temperature than those which are more rare, though we are far from having any perfect knowledge in this respect.

84
Difficulty
arising from
the suppo-
sition that
heat diffu-
ses itself
equally.

But the greatest difficulty of all will be, on the supposition that heat is a fluid, and an omnipresent one (which it must be, or there would be some places where bodies could not be heated), to answer the question, Why are not all bodies of an equal temperature, excepting only the differences arising from their specific densities, which render some capable of containing a greater quantity than others?—The difficulty will not be lessened, though the omnipresence of the fluid should be given up, if we suppose, as is generally done, that heat has a tendency to diffuse itself equably every way. If it has this tendency, what hinders it from doing so? Why doth not the heat from the burning regions of the torrid zone diffuse itself equally all over the globe, and reduce the earth to one common temperature? This indeed might require time; but the experience of all ages has shown that there is not the least advance towards an equality of temperature. The middle regions of the earth continue as hot, and the polar ones as cold, as we have any reason to believe they were at the creation of the world, or as we have any reason to believe they will be while the world remains. This indeed is one of the many instances of the impropriety of establishing general laws from the trifling experiments we are capable of making, and which hold good only on the narrow scales on which we can make them, but are utterly insufficient to solve the phenomena of the great system of nature, and which can be solved only by observing other phenomena of the same system undisturbed by any manoeuvres of our own.

85
Another
from the
seeming
disappear-
ance of the
heat.

86
Dr Craw-
ford's solu-
tion.

Again, supposing the objection already made could be got over, and satisfactory reasons should be given why an equilibrium of temperature in the earth and its atmosphere should never be obtained, it will by no means be easy to tell what becomes of the heat which is communicated to the earth at certain times of the year. This difficulty, or something similar, Dr Crawford seems to have had in view when treating of the effects of the evolution and absorption of heat. Thus, says he, "the Deity has guarded against sudden vicissitudes of heat and cold upon the surface of the earth."

"For if heat were not evolved by the process of congelation, all the waters which were exposed to the influence of the external air, when its temperature was

reduced below 32° , would speedily become solid; and, at the moment of congelation, the progress of cooling would be as rapid as it was before the air had arrived at its freezing point.

"This is manifest from what was formerly observed respecting the congelation of different fluids. It was shown, that if the velocities of the separation of heat were equal, the times of the congelation would be in proportion to the quantities of heat which the fluids gave off from an internal source in the freezing process. Whence it follows, that if no heat were evolved, the congelation would be instantaneous.

"In the present state of things, as soon as the atmosphere is cooled below 32° , the waters begin to freeze, and at the same time to evolve heat; in consequence of which, whatever may be the degree of cold in the external air, the freezing mass remains at 32° , until the whole is congealed; and as the quantity of heat extricated in the freezing of water is considerable, the progress of congelation in large masses is very slow.—That the absorption and extrication of heat in the melting and freezing of bodies has a tendency to retard the progress of these processes, is remarked by Mr Wilkie in his Essay on Latent Heat.—The same doctrine is likewise taught by Dr Black in his lectures.

"In the northern and southern regions, therefore, upon the approach of winter, a quantity of elementary fire is extricated from the waters, proportional to the degree of cold that prevails in the atmosphere. Thus the severity of the frost is mitigated, and its progress retarded; and it would seem that, during this retardation of the cooling process, the various tribes of animals and vegetables which inhabit the circumpolar regions gradually acquire power of resisting its influence.

"On the contrary, if, in the melting of ice, a quantity of heat were not absorbed, and rendered insensible, that substance, when it was exposed to a medium warmer than 32° , would speedily become fluid, and the process of heating would be as rapid as if no alteration in its form had taken place. If things were thus constituted, the vast masses of ice and snow which are collected in the frigid zones would, upon the approach of summer, suddenly dissolve, and great inundations would annually overflow the regions near to the poles.

"But by the operation of the law of the absorption of heat when the ice and snow upon the return of spring have arrived at 32° , they begin to melt, and at the same time to imbibe heat: during this process, a large quantity of elementary fire becomes insensible; in consequence of which the earth is slowly heated, and those gradual changes are produced which are essential to the preservation of the animal and vegetable kingdoms.

"We may remark, in the last place, that this law not only resists sudden changes of temperature, but that it likewise contributes to a more equal distribution of the principle of heat throughout the various parts of the earth, in different seasons and climates. Thus the diurnal heats are moderated by the evaporation of the waters on the earth's surface, a portion of the fire derived from the sun being absorbed and extinguished by the vapours at the moment of their ascent. On the approach of night the vapours are again condensed, and falling in the form of dew, communicate

and that all inanimate bodies, when heated and placed in a cold medium, continually lose heat, till in process of time they are brought to the state of the surrounding medium.

"From this property of heat it follows, that the various classes of bodies throughout the earth, if they were not acted upon by external causes, would at length arrive at a common temperature when the heat would become quiescent; in like manner as the waters of the ocean, if not prevented by the winds and by the attractions of the sun and moon, would come to an equilibrium, and would remain in a state of rest. But as causes continually occur in nature to disturb the balance of heat as well as that of the waters of the ocean, those elements are kept in a constant fluctuation.

"II. Heat is contained in considerable quantities in all bodies when at the common temperature of the atmosphere.

"From the interesting experiments which were made on cold by Mr Wilson, we learn, that at Glasgow, in the winter of the year 1780, the thermometer on the surface of snow sunk 25 degrees below the beginning of Fahrenheit's scale.

"We are told by Dr Pallas, that in the deserts of Siberia, during a very intense frost, the mercury was found congealed in thermometers exposed to the atmosphere, and a quantity of that fluid in an open bowl placed in a similar situation, at the same time became solid. The decisive experiments of Mr Hutchins at Hudson's Bay prove, that the freezing point of mercury is very nearly 40° below the zero (or 0°) of Fahrenheit. From which it follows, that at the time of Dr Pallas's observation, the atmosphere in Siberia must have been cooled to minus 40. By a paper lately transmitted to the Royal Society we are informed, that the spirit-of-wine thermometer in the open air at Hudson's Bay fell to — 42 in the winter of 1785; and from the same communication we learn, that by a mixture of snow and vitriolic acid, the heat was so much diminished, that the spirit of wine sunk to — 80, which is 112 below the freezing point of water.

"Hence it is manifest, that heat is contained in considerable quantities in all bodies when at the common temperature of the atmosphere. It is plain, however, that the quantity inherent in each individual body is limited. This, I think, must be admitted, whatever be the hypothesis which we adopt concerning the nature of heat; whether we conceive it to be a force or power belonging to bodies, or an elementary principle contained in them. For those who consider heat as an element, will not suppose that an unlimited quantity of it can be contained in a finite body; and if heat be considered as a force or power, the supposition that finite bodies are actuated by forces or powers which are infinite is equally inadmissible.

"To place this in another light, we know that bodies are universally expanded by heat, excepting in a very few instances, which do not afford a just objection to the general fact; because, in those instances, by the action of heat a fluid is extricated that previously separated the particles from each other. Since, therefore, heat is found to expand bodies in the temperatures which fall within the reach of our observation, we may conclude that the same thing takes place in all temperatures."

Our author, by a set of very accurate and laborious experiments, determines that the expansions in mercury and some other fluids are proportionable to the quantities of heat applied; "from which (says he) it is manifest, that the quantities of heat in bodies are limited, because an infinite heat would produce an infinite expansion.

"It is manifest, that the number of degrees of sensible heat, as measured by the thermometer, and estimated from the beginning of the scale, must be the same in all bodies which have a common temperature; for by the first general fact it is proved, that heat has a constant tendency to diffuse itself uniformly over bodies till their temperatures become equal. From which it may be inferred, that if a quantity of heat were added to bodies absolutely cold, the same uniform diffusion would take place; and that if a thermometer, altogether deprived of its heat, were applied to such bodies, it would be equally expanded by them, the whole of the sensible heat which they had acquired being indicated by that expansion.

"III. If the parts of the same homogeneous substance have a common temperature, the quantity of absolute heat will be proportional to the bulk or quantity of matter. Thus the quantity of absolute heat in two pounds of water is double that which is contained in one pound when at the same temperature.

"IV. The dilatations and contractions of the fluid in the mercurial thermometer are nearly proportional to the quantities of absolute heat which are communicated to the same homogeneous bodies, or separated from them, as long as they retain the same form. Thus the quantity of heat required to raise a body four degrees in temperature by the mercurial thermometer, is nearly double that which is required to raise it two degrees, four times that required to raise it one degree, and so in proportion."

Thus we find, that Dr Black, Dr Irvine, Dr Crawford, and Dr Berkenhout, agree in speaking of fire or heat as a fluid substance distinct from all other bodies. Mr Kirwan, in his Treatise of Phlogiston, agrees in the same opinion. "Some (says he) have thought, that I should have included the matter of heat, or elementary fire, in the definition of inflammable air; but as fire is contained in all corporeal substances, to mention it is perfectly needless, except where bodies differ from each other in the quantity of it they contain." On the other hand, Mr Cavendish, Phil. Trans. lxxiv. p. 141. tells us, that "he thinks it more likely that there is no such thing as elementary heat:" but, as he gives no reason for this opinion, it seems probable that the greater part of philosophers either positively believe that heat is an elementary fluid distinct from all others, or find themselves obliged to adopt a language which necessarily implies it. The only difficulty which now remains therefore is, to affix a proper idea to the phrase *quantity of heat*, which we find universally made use of, without any thing to determine our opinions concerning it.

That we cannot speak of a *quantity* of fire or heat in the same sense as we speak of a quantity of water or any other fluid is evident, because we can take away the quantity of water which any substance contains, but cannot do so with heat. Nay, in many cases we are sure, that a substance very cold to the touch does

yet contain a very considerable quantity of heat. The vapour of water, for instance, may be made much colder than the usual temperature of the atmosphere without being condensed, when at the same time we are certain that it contains a great quantity of heat; and the same may be said of water, which, in the act of freezing, throws out a great quantity of heat without becoming colder; and in the act of melting absorbs as much without becoming warmer. It is not therefore by the mere presence or absence of this fluid that we can determine the real quantity of this fluid; nor does it appear that the word *quantity* can be at all accurately applied to the element itself, because we have no method of measuring it.

72
Dr Cleghorn's opinion.

Dr Cleghorn, in his inaugural dissertation *De Igne*, throws some light on this subject, by observing, that "the thermometer shows only the quantity of heat going out of a body, not that which is really contained in it:" and he also insists, that "we can neither assent to the opinion of Dr Boerhaave, who supposed that heat was distributed among bodies in proportion to their bulks; nor to the hypotheses of others, who imagined that they were heated in proportion to their densities." But in what proportion, then, are they heated; or how are we to measure the *quantity* which they really contain, seeing the thermometer informs us only of what they part with?

73
The latent heat of bodies cannot be measured.

As this point is by no means ascertained, we cannot form a direct idea concerning the absolute quantity of heat contained in any body; and therefore when we speak of quantities of this fluid, we must in fact, if we mean any thing, think of the sensible quantity flowing out of them; and though we should suppose the whole of this sensible heat to be removed, it would still be impossible for us to know how much remained in a latent state, and could not be dissipated. This difficulty will still appear the greater, if with Dr Cleghorn and others we suppose the fluid of heat to be subject to the laws of attraction and repulsion. This gentleman supposes, that the particles of heat (like the particles of electric fluid according to the Franklinian hypothesis) are repulsive of one another, but attracted by all other substances. "If any body (says he), heated beyond the common temperature of the air, is exposed to it, the heat flows out from it into the atmosphere, and diffuses itself equally all around till the air becomes of the same temperature with itself. The same happens to bodies suspended in *vacuo*. Hence it is justly concluded, that there exists between the particles of heat a repulsive power, by which they mutually recede from each other. Notwithstanding this repulsive power, however, the quantities of heat contained in different substances, even of the same temperature, are found to be altogether different; and from Dr Black's experiments it now appears, that the quantity of heat is scarce ever the same in any two different bodies: and hence we may conclude, that terrestrial bodies have a power of attracting heat, and that this power is different in different substances.—From these principles it evidently follows, that heat is distributed among bodies directly in proportion to their attracting powers, and inversely according to the repulsive power between the particles of heat themselves. Such is the distribution of heat among bodies in the neighbourhood of each other, and which is called the *equilibrium of heat*, be-

74
Dr Cleghorn's hypothesis concerning fire.

75
Equilibrium of heat defined.

cause the thermometer shows no difference of temperature among them. For seeing the heat is distributed according to the attracting power of each, the thermometer having also a proper attraction of its own, can show no difference in the attracting power of each; for which reason all bodies in the neighbourhood of each other are soon reduced to the same temperature."

Of the
Element
of Fire.

If we assent to Dr Cleghorn's hypothesis, the quantity of heat contained in any substance depends, in the first place, on the attracting power of that substance, which is altogether unknown; and, in the second place, on the repulsive powers of the particles of heat themselves, which are equally unknown. To determine the *quantity*, therefore, must be impossible. Neither will the mixture of two different fluids, as in Dr Black's experiments, assist us in the least; for though water, heated more than mercury, communicates a greater heat to that fluid than the latter does to water; this only shows that water more readily parts with some part of the heat it contains than mercury does, but has not the least tendency to discover the quantity contained in either.

76
The quantity of heat cannot be determined by this hypothesis.

Dr Crawford, as we have already seen, calls the *degree*, or, if we may vary the phrase, the *quantity of power or element* (fluid, if we may substitute a synonymous word) existing or present in any body, its *absolute heat*; and lays down a rule for determining the proportional quantities of heat in different bodies. "It will appear (says he) from the experiments afterwards recited, that if a pound of water and a pound of diaphoretic antimony have a common temperature, the quantity of absolute heat contained in the former is nearly four times that contained in the latter."—The manner in which he illustrates this is as follows.

77
Dr Crawford's method of determining the proportional quantities of heat.

"If four pounds of diaphoretic antimony at 20 be mixed with one pound of ice at 32, the temperature will be nearly 26: the ice will be cooled six degrees, and the antimony heated six. If we reverse the experiment, the effect will be the same. That is, if we take six degrees of heat from four pounds of antimony, and add it to a pound of ice, the latter will be heated six degrees. The same quantity of heat, therefore, which raises a pound of ice six degrees, will raise four pounds of antimony six degrees.

"If this experiment be made at different temperatures, we shall have a similar result. If, for example, the antimony at 15, or at any given degree below the freezing point, be mixed with the ice at 32, the heat of the mixture will be the arithmetical mean between that of the warmer and colder substance. And since the capacities of bodies are permanent as long as they retain the same form, we infer, that the result would be the same if the antimony were deprived of all its heat, and were mixed with the ice at 32. But it is evident, that in this case the ice would communicate to the antimony the half of its absolute heat. For if 200 below frost be conceived to be the point of total privation, the antimony will be wholly deprived of its heat when cooled to 200 degrees below 32, and the heat contained in the ice when at 32 will be 200 degrees. If we now suppose them to be mixed together, the temperature of the mixture will be half the excess of the hotter above the colder, or the ice will be

be cooled 100 degrees and the antimony heated 100. The one half of the heat, therefore, which was contained in the ice previous to the mixture will be communicated to the antimony; from which it is manifest, that after the mixture the ice and antimony must contain equal quantities of absolute heat.

"To place this in another light, it has been proved, that the same quantity of heat which raises a pound of ice six degrees will raise four pounds of antimony six degrees. And as the capacities of bodies, while they retain the same form, are not altered by a change of temperature; it follows, that the same quantity of heat which raises the ice 200 degrees, or any given number of degrees, will raise the antimony an equal number of degrees.

"A pound of ice, therefore, and four pounds of antimony, when at the same temperature, contain equal quantities of absolute heat. But it appears from the third general fact (n^o 67.), that four pounds of antimony contain four times as much absolute heat as one pound of antimony; and hence the quantity of absolute heat in a pound of ice is to that in a pound of antimony as four to one."

78
His method
insufficient.

From this quotation it is evident, that, notwithstanding all the distinctions which Dr Crawford has laid down betwixt absolute heat and temperature, it is only the *quantity* of the latter that can be measured; and all that we can say concerning the matter is, that when certain bodies are mixed together, some of them part with a greater quantity of heat than others; but how much they *contain* must remain for ever unknown, unless we can fall on some method of measuring the quantity of heat as we do that of any other fluid.

79
Nicholson's
account of
the theories
of heat.

Mr Nicholson, who has collected the principal opinions on the subject of heat, seems undetermined whether to believe the doctrine of Boyle or of Boerhaave on the subject. "There are two opinions (says he) concerning heat. According to one opinion, heat consists in a vibratory motion of the parts of bodies among each other, whose greater or less intensity occasions the increase or diminution of temperature. According to the other opinion, heat is a subtle fluid that easily pervades the pores of all bodies, causing them to expand by means of its elasticity or otherwise. Each of these opinions is attended with its peculiar difficulties. The phenomena of heat may be accounted for by either of them, provided certain suppositions be allowed to each respectively; but the want of proof of the truth of such suppositions renders it very difficult, if not impossible, to decide as yet whether heat consists merely in motion or in some peculiar matter. The word *quantity*, applied to heat, will therefore denote either motion or matter, according to the opinion made use of, and may be used indefinitely without determining which.

80
Advantages of the
doctrine
that heat
is caused
by vibra-
tion.

"The chief advantage which the opinion that heat is caused by mere vibration possesses, is its great simplicity. It is highly probable, that all heated bodies have an intestine motion, or vibration of their parts; and it is certain that percussion, friction, and other methods of agitating the minute parts of bodies, will likewise increase their temperature. Why, then, it is demanded, should we multiply causes, by supposing the existence of an unknown fluid, when the mere vi-

No 70.

bration of parts which is known to obtain may be applied to explain the phenomena?"

To this the reply is obvious, that the vibration of parts is an *effect*; for matter will not begin to move of itself: and if it is an effect, we must suppose a cause for it; which, though we should not call it a fluid, would be equally unknown and inexplicable with that whose existence is asserted by those who maintain that fire is a fluid *per se*. Dr Cleghorn, however, in the dissertation already quoted, asserts, that "heat is occasioned by a certain fluid, and not by motion alone, as some eminent writers have imagined: because, 1. Those who have adopted the hypothesis of motion could never even prove the existence of that motion for which they contended; and though it should be granted, the phenomena could not be explained by it. 2. If heat depended on motion, it would instantaneously pass through an elastic body; but we see that heat passes through bodies slowly like a fluid. 3. If heat depended on vibration, it ought to be communicated from a given vibration in proportion to the quantity of matter; which is found not to hold true in fact. On the other hand, there are numberless arguments in favour of the opinion that heat proceeds from elementary fire. 1. Mr Locke hath observed, that when we perceive a number of qualities always existing together, we may gather from thence that there really is some substance which produces these qualities. 2. The hypothesis of elementary fire is simple and agreeable to the phenomena. 3. From some experiments made by Sir Isaac Newton, it appears, that bodies acquire heat and cold *in vacuo*, until they become of the same temperature with the atmosphere; so that heat exists in the absence of all other matter, and is therefore a substance by itself."

But though these and other arguments seem clearly to establish the point that fire or heat is a distinct fluid, we are still involved in very great difficulties concerning its nature and properties. If it be supposed a fluid, it is impossible to assign any limits to its extent; and we must of necessity likewise suppose that it pervades the whole creation, and consequently constitutes an absolute plenum, contrary to a fundamental principle of the received system of natural philosophy. But if this is the case, it is vain to talk of its being absorbed, accumulated, collected, or attracted by different bodies, since it is already present in all points of space; and we can conceive of terrestrial bodies no otherwise than as sponges thrown into the ocean, each of which will be as full of fluid as it can hold. The different capacities will then be similar to the differences between bits of wood, sponge, porous stones, &c. for containing water; all of which depend entirely on the structure of the bodies themselves, and which, unless we could separate the water by pressure, or by evaporation, would be for ever unknown. Supposing it were impossible to collect this water in the manner we speak of, we could only judge of the quantity they contained by the degree to which they swelled by being immersed in it. It is easy to see, however, that such a method of judging would be very inadequate to the purpose, as substances might contain internal cavities or pores in which water could lodge without augmenting the external bulk. This would suggest another method of judging of the quantity, namely, the specific gravity;

83
Difficulties
concerning
the nature
and properties
of fire.

Element
of Fire.

vity; and we might reasonably suppose, that substances of the greatest specific gravity would contain the smallest quantity of water, though still we could by no means determine what quantity they did contain, unless we could lay hold of the element itself.

This seems to be very much the case with elementary fire, if we suppose it to be a fluid *per se*. We judge of its presence by the degree of expansion which one heated body communicates to another: but this is only similar to the calculation of the quantity of moisture a sponge or any other body contains, by what it communicates to wood when it comes into contact with it; which never could be supposed to carry the least pretensions to accuracy, though we should ascertain it with all imaginable exactness. It is likewise probable that the most dense bodies contain the smallest quantity of fire, as they generally communicate less when heated to an equal temperature than those which are more rare, though we are far from having any perfect knowledge in this respect.

84
Difficulty
arising from
the suppo-
sition that
heat diffu-
ses itself
equally.

But the greatest difficulty of all will be, on the supposition that heat is a fluid, and an omnipresent one (which it must be, or there would be some places where bodies could not be heated), to answer the question, Why are not all bodies of an equal temperature, excepting only the differences arising from their specific densities, which render some capable of containing a greater quantity than others?—The difficulty will not be lessened, though the omnipresence of the fluid should be given up, if we suppose, as is generally done, that heat has a tendency to diffuse itself equably every way. If it has this tendency, what hinders it from doing so? Why doth not the heat from the burning regions of the torrid zone diffuse itself equally all over the globe, and reduce the earth to one common temperature? This indeed might require time; but the experience of all ages has shown that there is not the least advance towards an equality of temperature. The middle regions of the earth continue as hot, and the polar ones as cold, as we have any reason to believe they were at the creation of the world, or as we have any reason to believe they will be while the world remains. This indeed is one of the many instances of the impropriety of establishing general laws from the trifling experiments we are capable of making, and which hold good only on the narrow scales on which we can make them, but are utterly insufficient to solve the phenomena of the great system of nature, and which can be solved only by observing other phenomena of the same system undisturbed by any manoeuvres of our own.

85
Another
from the
seeming
disappear-
ance of the
heat.

86
Dr Craw-
ford's solu-
tion.

Again, supposing the objection already made could be got over, and satisfactory reasons should be given why an equilibrium of temperature in the earth and its atmosphere should never be obtained, it will by no means be easy to tell what becomes of the heat which is communicated to the earth at certain times of the year. This difficulty, or something similar, Dr Crawford seems to have had in view when treating of the effects of the evolution and absorption of heat. Thus, says he, "the Deity has guarded against sudden vicissitudes of heat and cold upon the surface of the earth."

"For if heat were not evolved by the process of congelation, all the waters which were exposed to the influence of the external air, when its temperature was

reduced below 32° , would speedily become solid; and, at the moment of congelation, the progress of cooling would be as rapid as it was before the air had arrived at its freezing point.

Element
of Fire.

"This is manifest from what was formerly observed respecting the congelation of different fluids. It was shown, that if the velocities of the separation of heat were equal, the times of the congelation would be in proportion to the quantities of heat which the fluids gave off from an internal source in the freezing process. Whence it follows, that if no heat were evolved, the congelation would be instantaneous.

"In the present state of things, as soon as the atmosphere is cooled below 32° , the waters begin to freeze, and at the same time to evolve heat; in consequence of which, whatever may be the degree of cold in the external air, the freezing mass remains at 32° , until the whole is congealed; and as the quantity of heat extricated in the freezing of water is considerable, the progress of congelation in large masses is very slow.—That the absorption and extrication of heat in the melting and freezing of bodies has a tendency to retard the progress of these processes, is remarked by Mr Wilkie in his Essay on Latent Heat.—The same doctrine is likewise taught by Dr Black in his lectures.

"In the northern and southern regions, therefore, upon the approach of winter, a quantity of elementary fire is extricated from the waters, proportional to the degree of cold that prevails in the atmosphere. Thus the severity of the frost is mitigated, and its progress retarded; and it would seem that, during this retardation of the cooling process, the various tribes of animals and vegetables which inhabit the circumpolar regions gradually acquire power of resisting its influence.

87
Severity of
the cold in
the north-
ern re-
gions miti-
gated by
the pro-
duction of
ice.

"On the contrary, if, in the melting of ice, a quantity of heat were not absorbed, and rendered insensible, that substance, when it was exposed to a medium warmer than 32° , would speedily become fluid, and the process of heating would be as rapid as if no alteration in its form had taken place. If things were thus constituted, the vast masses of ice and snow which are collected in the frigid zones would, upon the approach of summer, suddenly dissolve, and great inundations would annually overflow the regions near to the poles.

88
Inundations
prevented
by the flow-
ness with
which con-
gealed wa-
ter melts.

"But by the operation of the law of the absorption of heat when the ice and snow upon the return of spring have arrived at 32° , they begin to melt, and at the same time to imbibe heat: during this process, a large quantity of elementary fire becomes insensible; in consequence of which the earth is slowly heated, and those gradual changes are produced which are essential to the preservation of the animal and vegetable kingdoms.

"We may remark, in the last place, that this law not only resists sudden changes of temperature, but that it likewise contributes to a more equal distribution of the principle of heat throughout the various parts of the earth, in different seasons and climates. Thus the diurnal heats are moderated by the evaporation of the waters on the earth's surface, a portion of the fire derived from the sun being absorbed and extinguished by the vapours at the moment of their ascent. On the approach of night the vapours are again condensed, and falling in the form of dew, communicate

89
Equal di-
stribution
of heat pro-
moted by
its absorp-
tion and
evolution.

Element
of Fire.

to the air and to the earth the fire which they had imbibed during the day.

"It was before shown, that, in the regions near to the poles, when the vernal and summer heats prevail, provision is made for tempering the severity of the winter cold, a quantity of elementary fire, upon the dissolution of the ice and snow, being absorbed by the waters, and deposited, as it were, in a great magazine for the purpose of mitigating the intensity of the cold when the frost returns.

90
Heat of the
torrid zone
thus miti-
gated.

"From the experiments of Hales, Halley, and Watson, it appears, that vast quantities of water are continually converted into vapour by the action of the solar rays upon the portion of the earth's surface which is exposed to the light; and by the celebrated discovery of Dr Black, it is proved, that, in the process of evaporation, much elementary fire is absorbed. It is manifest, that this cause will have a powerful influence in mitigating the intensity of the heat in the torrid zone, and in promoting a more equal diffusion of it through the earth. For a considerable portion of the heat, which is excited by the action of the solar rays upon the earth's surface within the tropics, is absorbed by the aqueous vapours, which being collected in the form of clouds, are spread like a canopy over the horizon, to defend the subjacent regions from the direct rays of the sun. A great quantity of elementary fire is thus rendered insensible in the torrid zone, and is carried by the dispersion of the vapours to the north and to the south, where it is gradually communicated to the earth when the vapours are condensed."

91
This solu-
tion totally
insufficient
to remove
the difficul-
ty.

That all this takes place, as the Doctor has advanced, cannot be denied; but, by allowing it, the difficulty is not removed in the smallest degree, as will appear from a due consideration of the phenomena which he himself has mentioned.—He owns that the sun communicates fire to the earth: the question is, What becomes of it, seeing the emission is continual? In summer, the air, the earth, and the water, are heated to a certain degree. On the sun's declining southward, the air first loses its heat. Whither does it go? It does not ascend into the higher regions of the atmosphere, for these are constantly found colder than the parts below. It does not descend to the earth and water; for these give out the quantity they had absorbed, as Dr Crawford observes. Neither does it go laterally to the southern regions; for they are constantly very hot, and ought to impart their heat to those farther north, instead of receiving any from them. How comes it then, that the atmosphere seems perpetually to receive heat without ever being satiated? or if the heat cannot be found going off either upwards, downwards, or sideways, how are we to account for its disappearance?

92
Heat most
probably
the action
of an om-
nipresent
fluid.

This question seems to be altogether unanswerable on the supposition that heat is occasioned by the mere presence of a fluid; but if we suppose it to be only a particular mode of action of an omnipresent fluid, the whole difficulty vanishes at once.—On this supposition indeed the question will naturally arise, Whence does this motion proceed, or by what is its action in general determined? Dr Berkenhout, in enumerating the properties of matter, exempts fire from two of those usually ascribed to other material substances, viz. gravitation and the *vis inertiae*. "According to the

93
Fire seems
destitute of
gravity and
vis inertiae.

philosophers (says he), matter cannot move without being either impelled or attracted. I doubt much whether this be true of fire, and whether, when uncombined, motion be not one of its essential properties.—Gravitation seems also to be no property of fire, which moves with equal facility in all directions, and may be accumulated in hard bodies to any degree without increasing their weight. Fire, being the cause of volatility, seems rather to be in constant counteraction to gravity."

But however essential we may suppose the motion of fire to be to it, there cannot be any self-existent mobility in its parts, otherwise it would soon be diffused equally throughout the universe, and the temperature of the whole reduced to an equilibrium. According to the present constitution of nature, we see that the distribution of heat is principally owing to the sun; and what we call its *quantity*, depends on the position of the sun with regard to terrestrial objects and the length of time they are exposed to his rays. Heat is not produced while the rays have a direct passage; and therefore fluids through which they pass easily, as air, are not heated by the rays of the sun. But when the rays are impeded in their course, and reflected in considerable quantity, a degree of heat takes place, which is always greater or less in proportion to the intensity of the rays.—In the reflecting substance, the heat will be comparatively greater in proportion to the quantity of rays which are absorbed or stopped in their course by it; but in any substance interposed betwixt the sun and the reflecting body, the heat is proportionable to the quantity of rays reflected.—Now it is plain, that when the particles of light fall upon any opaque substance, and enter its pores, which by their extreme subtilty they are well calculated to do, they must make an attempt to pass directly through it in their natural course; but as this cannot be done, they will push laterally, and in all directions, in consequence of being perpetually urged by the impulse of the light coming from the sun: and thus an action will be propagated in all directions as radii from a centre towards a circumference, which when it takes place in that subtle fluid always produces what we call *heat*.

In contemplating the system of nature, we perceive three kinds of fluids of extreme subtilty, and very much resembling one another, viz. fire, light, and electricity. That it should be agreeable to vulgar conceptions to suppose these all to be ultimately the same, is not surprising; and on examining the evidence of their identity, it will certainly be found exceedingly strong. They all agree in the property of exciting the sensation of heat in certain circumstances, and in not doing so in others. Fire, we know, in the common acceptation of the word, always does so; but when it assumes the latent and invisible state, as in the formation of vapour, it lays aside this seemingly essential property, and the vapour is cold to the touch.—Light, when collected into a focus by a burning-glass, i. e. when its rays converge towards a centre, and diverge or attempt to diverge from one, produces heat also: and so does the electric fluid; for it has been found that the aura converging from a very large conductor to the point of a needle, is capable of setting on fire a small cartridge of gunpowder, or a quantity of tinder, surrounding it*. There seems also to be a connection betwixt

fire and electricity in another way; for in proportion as heat is diminished, or the bodies are cooled, electricity succeeds in its place. Thus all electric bodies by heat become conductors of electricity, and cannot be excited or made to show any signs of containing that fluid; but as soon as the heat is removed, their electric property returns. Water is naturally a conducting substance: by being frozen its conducting power is lessened, which shows an approach to electricity; and, by being cooled down to 20° below 0 of Fahrenheit, the ice actually becomes electric, and will emit sparks by friction like glass*. The atmosphere is a natural electric: but by a certain degree of heat it loses this property, and becomes a conductor; nor is there any doubt that its electric properties are increased in proportion to the degree of cold imparted to it. In the winter time, therefore, we must consider the frozen surface of the earth, the water, and the atmosphere of the polar regions, as forming one electrical machine of enormous magnitude; for the natural cold of these countries is often sufficient to cool the water to more than 20° below 0, and consequently to render it an electric. That this is really the case, appears from the excessively bright aurora borealis and other electric appearances, far exceeding any thing observed in this country. In the summer time, however, no such appearances are to be seen, nor any thing remarkable except an excessive heat from the long continuance of the sun above the horizon. This quantity of heat then being succeeded by a proportionable quantity of electricity in winter, it is impossible to avoid concluding that the heat in summer becomes electric fluid in winter, which, going off through the celestial expanse, returns again to the grand source of light and heat from which it originally came; thus making room for the succeeding quantities which are to enliven the earth during the following summer.

Thus the disappearance of heat in winter, and of electricity in summer, in these countries, will be very naturally and easily accounted for. It is true, that the phenomena of thunder and lightning show the existence of this fluid in vast quantities during the summer season: but these phenomena are only partial, and though formidable to us, are trifling in comparison with the vast quantities of electric matter discharged by the continual flashing of the aurora borealis, not to mention the fire-balls and meteors called *falling stars*, which are very often to be seen in the northern countries. In the summer-time, the air which is an electric, heated by the rays of the sun, is excited or made to part with the fluid to the vapours contained in it; and it is the unequal or opposite electricity of the clouds to one another, or to the earth, which produces the lightning. But in winter, when the air, earth, and vapours, all become electric, they cannot discharge sparks from one to another as before; but the whole, as one connected and vast electrified apparatus, discharges the matter almost in a continued stream for many months.

From a consideration of these and other phenomena of nature, as well as of the best experiments which have hitherto been made, we must consider fire in the abstract as an omnipresent fluid, of such subtilty as to pervade all terrestrial substances. When by any means it is made to diverge every way as from a centre, there it operates as heat; expands, rarefies, or burns, according

to the intensity of its action. Proceeding in straight and parallel lines, or such as diverge but little, it acts as light, and shows none of that power discoverable in the former case, though this is easily discoverable by making it converge into a focus. In a quiescent state, or where the motion is but little, it presses on the surfaces of bodies, contracts and diminishes them every way in bulk, forces out the expanding fluid within their pores, and then acts as cold. In this case also, being obliged to sustain the vehement action of that part of the fluid which is in motion, it flies with violence to every place where the pressure is lessened, and produces all the phenomena of ELECTRICITY.

§ 1. Of the Nature of Heat.

The manner in which the phenomena of heat may be solved and its nature, understood, will appear from the following propositions.

1. It is in all cases observed, that when light proceeds in considerable quantity from a point, diverging as the radii of a circle from its centre, there a considerable degree of heat is found to exist, if an opaque body, having no great reflective power, is brought near that point.

2. This action of the light, therefore, may be accounted the ultimate cause of heat, without having recourse to any farther suppositions; because nothing else besides this action is evident to our senses.

3. If the point from which the rays are emitted is placed in a transparent medium, such as air or water, that medium, without the presence of an opaque body, will not be heated.

4. Another cause of heat, therefore, is the resistance of the parts of that body on which the light falls, to the action mentioned in Prop. 1. Where this resistance is weak, as in the cases just mentioned, the heat is either nothing, or very little.

5. If a body capable of reflecting light very copiously is brought near the lucid point, it will not be heated*.

6. A penetration of the light, therefore, into the substance of the body, and likewise a considerable degree of resistance on the part of that body to the action of the light, are the requisites to produce heat.

7. Those bodies ought to conceive the greatest degrees of heat into whose substance the light can best penetrate, *i. e.* which have the least reflective power, and which most strongly resist its action; which is evidently the case with black and solid substances.

8. By heat all bodies are expanded in their dimensions every way, and that in proportion to their bulk and the quantity of heat communicated to them.

9. This expansion takes place not only by an addition of *sensible* heat, but likewise of that which is *latent*. Of this last we have a remarkable instance in the case of snow mixed with spirit of nitre. The spirit of nitre contains a certain quantity of latent heat, which cannot be separated from it without effecting a change on the spirit itself; so that, if deprived of this heat, it would no longer be spirit of nitre.—Besides this, it contains a quantity of sensible heat, of a great part of which it may be deprived, and yet retain its characteristic properties as nitrous acid. When it is poured upon snow, the latter is immediately melted by the action of the latent heat in the acid. The snow cannot

Glass*.

Nature of
Heat.

be melted or converted into water, without imbibing a quantity of latent heat, which it receives immediately from the acid which melts it. But the acid cannot part with the heat without decomposition; to prevent which, its sensible heat occupies the place of that which has entered the snow and liquefied it. The mixture then becomes exceedingly cold, and the heat forces into it from all the bodies in the neighbourhood; so that, by the time it has recovered that quantity of sensible heat which was lost, or arrived at the temperature of the atmosphere around it, it will contain a considerably larger quantity of heat than it originally did, and is therefore observed to be expanded in bulk. Another instance of this expansive power of latent heat is in the case of steam, which always occupies a much larger space than the substance from which it was produced; and this whether its temperature is greater or less than the surrounding atmosphere.

10. The difference between latent and sensible heat, then, as far as we can conceive, is, that the expansive power of the former is directed only against the particles of which the body is composed; but that of the latter is directed also against other bodies. Neither doth there seem to be any difference at all between them farther than in quantity. If water, for instance, hath but a small quantity of heat, its parts are brought near each other, it contracts in bulk, and feels cold. Still, however, some part of the heat is detained among the aqueous particles, which prevents the fluid from congealing into a solid mass. But, by a continuation of the contracting power of the cold, the particles of water are at last brought so near each other that the internal or *latent* heat is forced out. By this discharge a quantity of air is also produced, the water is congealed, and the ice occupies a greater space than the water did; but then it is full of air-bubbles, which are evidently the cause of its expansion. The heat then becomes *sensible*, or, as it were, lies on the outside of the matter; and consequently is easily dissipated into the air, or communicated to other bodies. Another way in which the latent heat may be extricated is by a constant addition of sensible heat. In this case the body is first raised into vapour, which for some time carries off the redundant quantity of heat. But as the quantity of this heat is continually increased, the texture of the vapour itself is at last totally destroyed. It becomes too much expanded to contain the heat, which is therefore violently thrown out on all sides into the atmosphere, and the body is said to burn, or be on fire. See COMBUSTION, FLAME, and IGNITION.

11. Hence it follows, that those bodies which have the least share of latent heat, appear to have the greatest quantity of sensible heat; but this is only in appearance, for the great quantity they seem to contain is owing really to their inability to contain it. Thus, if we can suppose a substance capable of transmitting heat through it as fast as it received it; if such a substance was set over a fire, it would be as hot as the fire itself, and yet the moment it was taken off, it would be perfectly cool, on account of its incapacity to detain the heat among the particles of which it was composed.

12. The heat, therefore, in all bodies consists in a certain violent action of the elementary fire within

them tending from a centre to a circumference, and thus making an effort to separate the particles of the body from each other, and thereby to change its form or mode of existence. When this change is effected, bodies are said to be dissipated in vapour, calcined, vitrified, or burnt, according to their different natures.

13. Inflammable bodies are such as are easily raised in vapours; that is, the fire easily penetrates their parts, and combines with them in such quantity, that, becoming exceedingly light, they are carried up by the atmosphere. Every succeeding addition of heat to the body increases also the quantity of latent heat in the vapour, till at last, being unable to resist its action, the heat breaks out all at once, the vapour is converted into flame, and is totally decomposed. See the article FLAME, and Prop. 10.

14. Uninflammable bodies are those which have their parts more firmly connected, or otherwise disposed in such a manner, that the particles of heat cannot easily combine with them or raise them into vapour.

15. Heat therefore being only a certain mode of the action of elementary fire, it follows, that the capacity of a body for containing it, is only a certain constitution of the body itself, or a disposition of its parts, which can allow the elementary fire contained in it to exert its expansive power upon them without being dissipated on other bodies. Those substances which allow the expansive power of the fire to operate on their own particles are said to contain a great deal of heat; but those which throw it away from themselves upon other bodies, though they feel very hot, yet philosophically speaking they contain very little heat.

16. What is called the *quantity* of heat contained in any substance, if we would speak with the strictest propriety, is only the apparent force of its action, either upon the parts of the body itself, or upon other bodies in its neighbourhood. The expansive force of the elementary fire contained in any body upon the parts of that body, is the *quantity of latent heat* contained in it; and the expansive force of the fire exerted upon other bodies which touch or come near it, is the *quantity of sensible heat* it contains.

17. If what we call *heat* consists only in a certain action of that fluid called *elementary fire*, namely, its expansion, or acting from a centre to a circumference, it follows, that if the same fluid act in a manner directly opposite to the former, or press upon the particles of a body as from a circumference to a centre, it will then produce effects directly opposite to those of heat, i. e. it will then be absolute *cold*, and produce all the effects already attributed to *COLD*. See that article.

18. If heat and cold then are only two different modifications of the same fluid, it follows, that if a hot body and a cold one are suddenly brought near each other, the heat of the one ought to drive before it a part of the cold contained in the other, i. e. the two portions of elementary fire acting in two opposite ways, ought in some measure to operate upon one another as any two different bodies would when driven against each other. When a hot and a cold body therefore are brought near each other, that part of the cold body farthest from the hot one ought to become colder than before, and that part of the hot body farthest from the cold one ought to become hotter than before.

General Effects of Heat.

19. For the same reason, the greatest degree of cold in any body ought to be no obstacle, or at least very little, to its conceiving heat, when put in a proper situation. Cold air, cold fuel, &c. ought to become as intensely heated, and nearly as soon, as that which is hotter.

The two last propositions are of great importance. When the first of them is thoroughly established, it will confirm beyond a doubt, that cold is a *positive*, as well as heat; and that each of them has a separate and distinct power, of which the action of its antagonist is the only proper limit; *i. e.* that heat can only limit the power of cold, and *vice versa*. A strong confirmation of this proposition is the experiment related by M. Geoffroy; an account of which is given under the article *COLD*. Another, but not so well authenticated, is related under the article *CONGELATION*. — De Luc's observation also, mentioned by Dr Cleghorn, affords a pretty strong proof of it; for if the lower parts of the atmosphere are cooled by the passage of the sun's rays at some distance above, and it hath been already shown that they do not *attract* the heat from the lower parts, it follows, that they must *expel* part of the cold from the upper regions. — The other proposition, when fully established, will prove, that heat and cold are really convertible into one another; which indeed seems not improbable, as we see that fires will burn with the greatest fierceness during the time of intense frosts, when the coldest air is admitted to them; and even in those dismal regions of Siberia, when the intense cold of the atmosphere is sufficient to congeal quicksilver, it cannot be doubted that fires will burn as well as in this country; which could not happen if heat was a fluid *per se*, and capable of being carried off, or absolutely diminished in quantity, either in any part of the atmosphere itself, or in such terrestrial bodies as are used for fuel.

§ 2. Of the general Effects of Heat.

HAVING said thus much concerning the nature of heat in general, we come now to a particular explanation of its several effects, which indeed constitute the whole of the active part of chemistry. — These are,

I. *Expansion*, or increase of bulk in every direction. This is a necessary consequence of the endeavour which the fluid makes to escape in all directions, when made to converge into a focus. The degree of expansion is unequal in different bodies, but in the same body is always proportionable to the degree of heat applied. There are two different instruments in use for ascertaining the degrees of expansion; and as we have already shown, that the degree of heat can only be known by the expansion, these effects of heat upon the instrument are usually taken for the degrees of heat themselves. These instruments are called the *THERMOMETER* and *PYROMETER*. The former is composed of a glass tube, with a globe or rather oval tube at one end, and exactly closed at the other: it is most usually filled with mercury or spirit of wine; but mercury is generally preferred on account of its expansions being more equable than those of any other fluid. It has the disadvantage, however, of being subject to congelation; which is not the case with spirit of wine, when very highly rectified. Spirit-of-wine

thermometers, therefore, ought not to be entirely disused, but seem rather a necessary part of the chemical apparatus, as well as those made with mercury.

As no thermometer made with any fluid can measure either the degrees of heat about the point at which it boils, or the degrees of cold below which it congeals, instruments have been contrived by which the expansion of solid bodies, though much less than what is occasioned by an equal degree of heat in a fluid, may become visible. These were usually called *Pyrometers*; but Mr Wedgwood has lately contrived a method of connecting the two together, in which the highest degree of heat, exceeding even that of a glass-house furnace, may be measured as accurately as the more moderate degrees by the common mercurial thermometer. See *THERMOMETER*.

Expansion in some cases does not appear to be the effect of heat, of which we have two remarkable instances, viz. of iron, which always expands in cooling after it has been melted; and of water, which expands with prodigious force in the act of freezing. The power with which iron expands in the act of passing from a fluid to a solid state, has never been measured, nor indeed does it seem easy to do so; but that of freezing water has been accurately computed. This was done by the Florentine Academicians, who having filled an hollow brass ball of an inch diameter with water, exposed it to a mixture of snow and salt, in order to congeal the water, and try whether its force was sufficient to burst the ball or not. The ball, being made very strong, resisted the expanding force of the water twice, even though a considerable part of its thickness had been pared off when it was perceived too strong at first. At the third time it burst; and by a calculation founded on the thickness of the globe and the tenacity of the metal, it was found that the expansive power of a spherule of water only one inch in diameter, was sufficient to overcome a resistance of more than 27,000 pounds, or 13 tons and an half.

A power of expansion so prodigious, little less than double that of the most powerful steam-engines, and exerted in so small a body, seemingly by the force of cold, was thought to be a very powerful argument in favour of those who suppose cold to be a positive substance as well as heat; and indeed contributed not a little to embarrass the opposite party. Dr Black's discovery of latent heat, however, has now afforded a very easy and natural explication of this phenomenon. He has shown, that, in the act of congelation, water is not cooled more than it was before, but rather grows warmer: that as much heat is discharged, and passes from a latent to a sensible state, as, had it been applied to water in its fluid state, would have heated it to 135°. In this process the expansion is occasioned by a great number of minute bubbles suddenly produced. These were formerly supposed to be formed of cold in the abstract; and to be so subtle, that, insinuating themselves into the substances of the fluid, they augmented its bulk, at the same time that, by impeding the motion of its particles upon each other, they changed it from a fluid to a solid. Dr Black, however, has demonstrated, that these are only air extricated during the congelation; and to the extrication of this air he very justly attributes the prodigious expansive force exerted by freezing water. The only

Impossibility of determining the quantity of heat any body contains.

113
Mr Nicholson's account of the capacities of bodies for containing heat, &c.

only question, therefore, which now remains is, By what means this air comes to be extricated, and to take up more room than it naturally does in the fluid? To this we can scarce give any other answer, than that part of the heat which is discharged from the freezing water combines with the air in its unelastic state, and, by restoring its elasticity, gives it that extraordinary force, as we see also in the case of air suddenly extricated in the explosion of gunpowder. Thus expansion, even in the case of freezing, is properly an effect of heat; and must therefore be considered as a phenomenon uniformly and certainly attending the action of heat, and in all cases to be ascribed to it.

The only way in which the element or fluid of fire can be supposed to act, and the way in which we can have a rational idea of its being able to produce both heat and cold according to the diversity of its action, has been already explained so fully, that it is needless at present to enter into any further discussion of the subject. It will easily appear, that the capacity for containing heat is nothing different from the action of heat upon that body in expanding, and at last altering its form in such a manner, as either to be able to insinuate itself among the particles in much greater quantity than before, still retaining its internal action, though the external one becomes imperceptible; or scattering them in such a manner, that it breaks forth in great quantity in its peculiar appearances of fire and light; in the former case producing vapour or smoke, and in the latter flame, as shall afterwards be more fully explained. It must likewise appear, that to determine the quantity of heat in any body is altogether impossible: and with regard to the lowest degree of heat, or a total expulsion of that fluid, so far from being able to determine what it is, the probability must be, that nature does not admit of any such thing; for if heat consists in the expansive action of a certain fluid, and cold in its opposite or contractile action, there is very little reason to suppose that the constitution of nature will allow any one of these actions entirely to cease, as it does not appear by what means it could again be renewed. Cold, as we have already seen, always tends to produce electricity; and the connection betwixt that and fire is so strong, that we cannot suppose the former to be carried to any great extreme without producing the latter. Whatever we may therefore suppose concerning the capacities of different bodies for containing heat, or concerning the point of total privation of heat, must be altogether void of foundation. A rule, however, has been given by Mr Kirwan for finding the point of total privation, which, together with its demonstration, we shall subjoin; and as it is necessary for the better understanding of this, to call to remembrance what has been said concerning the difference between the temperatures and specific heats of bodies, we shall insert an epitome of the doctrine from Mr Nicholson.

"If two equal bodies of different kinds and temperatures be brought into contact, the common temperature will seldom, if ever, be the mean betwixt the two original temperatures; that is to say, the surplus of heat in the hotter body will be unequally divided between them, and the proportions of this surplus retained by each body will express their respective dispositions, affinities, or capacities for heat.—If, there-

fore, a given substance, as for example fluid water, be taken as the standard of comparison, and its capacity for heat be called one, or unity, the respective capacities of their bodies may be determined by experiment; and expressed in numbers in the same manner as specific gravities usually are. And because it is established as well from reason as experiment, that the same capacity for heat obtains in all temperatures of a given body, so long as its state of solidity, fluidity, or vapour is not changed, it will follow, that the whole quantities of heat in equal bodies of a given temperature will be as those capacities. And as the respective quantities of matter, in bodies of equal volume, give the proportions of their specific gravities, so the respective quantities of heat in bodies of equal weight and temperature give the proportions of their specific heats.

"A greater capacity for heat, or greater specific heat, in a given body, answers the same purpose with respect to temperature as an increase of the mass; or the quantity of heat required to be added or subducted, in order to bring a body to a given temperature, will be as its capacity or specific heat.

"The capacities not only differ in various bodies, but also in the same body, according as it is either in a solid, fluid, or vaporous state. All the experiments hitherto made conspire to show, that the capacity, and consequently the specific heat, is greatest in the vaporous, less in the fluid, and least in the solid state.

"The quantity of heat that constitutes the difference between the several states, may be found in degrees of the thermometer. Thus, if equal quantities of water at 162° and ice at 32° of temperature be mixed, the ice melts, and the common temperature becomes 32° ; or otherwise, if equal quantities of frozen and fluid water, both at 23° , be placed in a like situation to acquire heat from a fire, the water will become heated to 162° , while the ice melts without acquiring any increase of temperature. In either case the ice acquires 130° of heat, which produces no other effect than rendering it fluid. Fluid water, therefore, contains not only as much more heat than ice, as is indicated by the thermometer, but also 130° , that is in some manner or other employed in giving it fluidity. And as fluid water cannot become ice without parting with 130° of heat besides what it had above 32° in its temperature; so also steam cannot become condensed into water without imparting much more heat to the matters it is cooled by, than water at the same temperature would have done.

"The heat employed in maintaining the fluid or vaporous form of a body, has been called latent heat, because it does not affect the thermometer.

"From the consideration of the specific heats of Mr Kirwan's theorem for finding the point of total privation of heat. the same body in the two states of fluidity and solidity, and the difference between those specific heats, is deduced a method of finding the number of degrees which denote the temperature of any body immediately after congelation, reckoned from the natural zero, or absolute privation of heat. The rule is; multiply the degrees of heat required to reduce any solid to a fluid state, by the number expressing the specific heat of the fluid: divide this product by the difference between the numbers expressing the specific heat of the body in each state; the quotient will be the number of

General Effects of Heat.

114

General Effects of Heat. of degrees of temperature, reckoned from an absolute privation of heat.

"This theorem is Mr Kirwan's, and may be proved thus. Let s represent the required temperature of the body just congealed, $l =$ the number of degrees that express the heat required to reduce it to fluidity, $n =$ the specific heat of the solid, and $m =$ the specific heat of the fluid. Then $s+l:s::m:n$. Whence

$s = \frac{ln}{m-n} =$ the temperature from the natural zero in thermometrical degrees of the fluid. But because the actual fall of the thermometer is to be produced by cooling the solid, must pay attention to its capacity. The quantity of heat required to produce a given change of temperature in a body is as its capacity; and consequently the changes of temperature, when the quantity of heat is given, will be inversely as the capacities: therefore, $n:m::\frac{ln}{m-n}:\frac{ln}{m-n}=s$, which is the rule above mentioned.

"If the data l , m , and n , be accurately obtained by experiment, in any one instance, and the difference between the zero of Fahrenheit's scale and the natural zero be thence found in degrees of that scale, this difference will serve to reduce all temperatures to the numeration which commences at the natural 0. So that s being known in all cases, if any two of the quantities l , m , or n , be given in any body, the other may be likewise had. For $l = \frac{sm-sn}{m}$; and $m = \frac{sn}{s-l}$ and $n = \frac{sm-lm}{s}$.

"To give an example of this curious rule, let it be required to determine how many degrees of refrigeration would absolutely deprive ice of all its heat? The degrees of heat necessary to melt ice are 130; and the specific heats of ice and water are as 9 to 10. The number 130 multiplied by 10, produces 1300, and divided by the difference between 9 and 10 quotes 1300: therefore if ice were cooled 1300 degrees below 32°, or to -1268 of Fahrenheit's scale, it would retain no more heat."

115 Fluidity to be ascribed to the absorption of heat.

II. Fluidity is another effect of heat, and is capable of taking place in all bodies hitherto known, when the fire is carried to a certain pitch. Theories have been invented, by which fluidity was ascribed to the smoothness and round figure of the particles whereof bodies were composed, and solidity to an angular or irregular figure. It has also been ascribed to a stronger degree of attraction between the parts of solids than of fluids. Dr Black, however, has shown, that in the case of melting ice, we are certainly to ascribe the acquired fluidity of the water to the absorption of heat. This was determined by a decisive experiment, in which he exposed a Florence-flask full of water to the atmosphere in a warm room, when he found that the heat in the air evidently left it, to flow into the ice in the bottle, and reduced it to fluidity. The air thus deprived of its heat, he felt sensibly descending like a cold blast from the bottle, and continuing to do so as long as any of the ice remained unthawed; yet after it was all melted, the temperature of the fluid was no more than 32°. Different degrees of heat are requisite for converting different solids into fluids, for which see the *Table of Degrees of HEAT*.

This theory receives an additional confirmation from the quantity of heat which is always known to be produced by the conversion of a fluid into a solid. And that this is really the case appears, 1. From what happens in the congelation of waters, it appears that ice is formed very slowly, and with several circumstances which support the theory.—Thus, if we expose equal quantities of water to the air, which is perhaps 10° below frost, and add to one of these a small quantity of salt or spirit of wine, and observe the cooling of each, we shall find them both grow gradually colder, until they arrive at the temperature of frost; after which the water containing the salt will continue to grow colder, until it has arrived at the temperature of the air, at the same time that only a small quantity of the other water is converted into ice. Yet were the common opinion just, it ought all to have been congealed by this time; instead of which, it is scarce grown a degree colder during the whole time. Its remaining at the same temperature for so long time, shows that it has been communicating heat to the atmosphere; for it is impossible that any body can remain in contact with another that is colder, without communicating heat to it. Whence then comes this heat? There must be some source adding to the sensible heat of the water, so as to keep up its temperature to the freezing point: and this source of heat must be very considerable; for it will continue to act for a very long time before the water is changed into ice; during all which time, even to the last drop, the water is not a degree colder than 32° of Fahrenheit's thermometer. This, therefore, is the latent heat of the water, which had formerly entered into it during its transition from ice to a fluid state.

A still stronger argument is derived from the following experiment; which evinces that the fluidity of water really depends upon its latent heat, and that the sensible heat is only a mean or condition to its containing the latent heat. This experiment consists in exposing water contained in a covered beer-glass to the air of a cold frosty night; and when the atmosphere is at the temperature of perhaps 10° or 12° below frost, the water will acquire that temperature without freezing: so that the fluidity of the water does not altogether depend on the quantity of sensible heat contained in it. The congelation, however, may be brought on by touching it with a bit of ice, with the extremity of a wire, by a shock upon the board, or otherwise disturbing it; and we then find the temperature suddenly raised up to 32°. This shows plainly, that the water has a disposition to retain the quantity of latent heat, upon which its fluidity must immediately and necessarily depend; and it retains it with a certain degree of force, so as to keep the water fluid in a temperature below that in which it usually parts with the latent heat and congeals. By disturbing it, however, we instantly bring on the congelation, which cannot take place without an extrication of the latent heat; which then, being changed into the ordinary or moveable heat, raises the thermometer as usual. The quantity of heat discharged from the first small portion of ice formed in the water is sufficient to prevent any more latent heat from separating, and consequently from any more ice being produced till more of the sensible heat is abstracted.

This doctrine extends not only to such bodies as are actually converted from a solid to a fluid; or from

General Effects of Heat.

121 Experiments by Dr Black on the conversion of water into vapour.

a fluid to a solid state, but to such as are in a kind of middle state betwixt solidity and fluidity; for every degree of softness depends on a certain degree of heat contained in the body. Thus, for instance, melted wax, allowed to cool slowly, soon becomes opaque and consistent; but it must be colder still before it attains its utmost degree of hardness. There is therefore a certain degree of heat below which every body is solid, and above which every one is fluid; the former being called the *congealing*, and the latter the *melting*, point of bodies.

By making experiments upon different substances, the Doctor was convinced that latent heat is the universal cause of fluidity; and the doctrine holds good in all the experiments that have hitherto been made upon spermaceti, bees-wax, and some of the metals. If they are melted, allowed to cool slowly, and a thermometer be immersed into them, we find, that as long as they continue fluid, their sensible heat diminishes very fast; but as soon as they begin to grow solid, the sensible heat continues greater than that of the air to which they are exposed; and during all this time it is communicating heat to the air, without having its sensible heat diminished: for the latent heat within the fluid gradually receives a sensible form, and keeps up the temperature, proving a source of sensible heat, which is communicated to the neighbouring bodies as well as the surrounding air. The softness and ductility of bodies depend on this also.

III. *Evaporation*. A third effect of the action of heat is that of converting bodies into vapour, by which they are rendered specifically lighter than the surrounding atmosphere, and enabled to rise in it. To account for this, many theories have been invented; but that of Dr Black, who accounts for it, as well as fluidity from the absorption of latent heat, is now universally received. The circumstances by which he proves and illustrates his doctrine are the following:

1. When we attend to the phenomena of boiling water, in a tea-kettle for instance, it may, when first put upon the fire, be about the temperature of 48° or 50° . In a quarter of an hour it will become heated to 212° . It then begins to boil, and has gained 162° of vapour in that time. Now, if the conversion of it into vapour depended on the quantity of sensible heat introduced, we may ask how long it will be necessary to raise it all in vapour? Surely another quarter of an hour should be sufficient; but this is far from being the case. Dr Black made some experiments upon this subject in conjunction with another gentleman. Having the opportunity of what is called a kitchen-table or a thick plate of cast iron, one end of which was made sensibly red-hot, they set upon this some iron vessels with circular flat bottoms, of about four inches diameter, and which contained a quantity of water. The temperature of the water was noted, as also when it began to boil; and when the whole of it was boiled away, it was found, that when set on the table its temperature had been 54° ; in four minutes it began to boil, and in that space of time received 158° degrees of heat. Had the evaporation, therefore, depended merely on the quantity of sensible heat introduced, it ought to have been dissipated entirely in a single minute more. It was, however, 18 minutes in dissipating; and therefore had received 807 degrees of heat before it was all evapo-

N^o 70.

rated. All this time, therefore, while the water continued to boil, it was receiving a great quantity of heat, which must have been flowing equally fast out of it; for the vessel was no hotter, and the iron plate continued equally hot, the whole time. The vessels were of different shapes, some of them cylindrical, some conical, others widening upwards; one of the designs of the experiment being to show how far the evaporation was retarded by the particular form of the vessels. By suspending a thermometer in the mouth of one of the evaporating vessels, the heat of the steam was found to be exactly 212° ; so that as the great quantity of heat absorbed was found neither to have remained in the water, nor to have been carried away by the steam in a sensible manner, we have nothing left to suppose, but that it flew off as one of the component parts of the steam in a latent state.

2. In an experiment to show the fixedness of the boiling point of water, Dr Black inclosed some of that fluid in a strong vial having a thermometer in it, and stopped close with a cork. By the application of heat he hoped now to be able to raise the thermometer some degrees above the boiling point, which would be the natural consequence of the confinement of the steam. When this was done, he pulled out the cork, and supposed that the water would now all fly out in vapour: but in this he was totally disappointed; a sudden and very tumultuous boiling ensued, which threw out some of the water; but though some quantity of steam likewise issued, the quantity of water was not considerably diminished. The vial had been heated to 20° above the boiling point, but almost instantly cooled down to 212° , when the cork was taken out.

3. Mr Watt, in making some experiments on the force of steam, had occasion to use Papin's digester, with a pipe proceeding from its side; the orifice of which was shut with a valve pressed down by one end of a lever. Thus he heated steam to 400° of Fahrenheit; after which, having suddenly struck off the lever, a quantity of steam flew out with considerable noise, and with such violence as to make an impression on the ceiling of the room; but this noise gradually diminished, and after ten minutes ceased entirely; and upon opening the machine, he found the greatest part of the water still remaining.

4. The change of sensible into latent heat in the formation of vapour, appears still more evident in the boiling of water *in vacuo*. Mr Boyle took a quantity of water which had been previously boiled to purge it of its air, and put it whilst hot under the receiver of an air-pump. In consequence of this it began again to boil, and continued boiling till it was only lukewarm, and it soon arrived at this temperature; so that in this case also the heat had disappeared during the conversion of the fluid into vapour. Others have repeated the experiment, as Boerhaave, Muschenbroek; and Robinson, who lectures on chemistry in Glasgow, says that the heat diminishes very fast till it comes to 90° or 95° , which seems to be the boiling point of water *in vacuo*. As a considerable part of the heat thus disappears, and is to be discovered neither in the water nor in the vapour, we must conclude that it enters the latter as part of its composition.

5. Thus also we may understand some curious experiments made by Dr Cullen upon ether and other volatile

General Effects of Heat.

122 Boiling point of water in vacuo determined by Mr Boyle.

123 And by Mr Robinson of Glasgow.

General Effects of Heat. 124
 Dr Cullen's experiments on cold produced by evaporation.
 volatile fluids. He employed some persons to make experiments upon the cold produced by evaporation; and willing to repeat them himself *in vacuo*, he put some of the most volatile liquors under the receiver of an air-pump. One of these was ether. It was contained in a glass, in which there was also placed some water. When the air was extracted, the ether began to boil, and to be converted into vapour, till it became so very cold that it froze the water contained in the vessel, though the temperature of the room was about 50° . Here therefore there was a quantity of heat which disappeared all of a sudden; which it is plain could not be owing to its having any communication with that of the atmosphere or other cold bodies, as they could not render it colder than they were themselves. Ether therefore is to be considered as a fluid so volatile, that were it not for the pressure of the atmosphere it would be perpetually in the state of vapour.

125
 Heat expelled in great quantity by the condensation of vapour.
 6. That this heat which enters into the vapour is not destroyed, but remains in a latent state, is easily proved; for we find that a great quantity of heat is expelled from vapour when it is condensed again to form the body it composed originally. This is easily ascertained by observing the quantity of heat communicated to the water in the refrigeratory of a still by any given quantity of liquid which comes over. Thus, if the refrigeratory contain 100 pounds of water, and the distillation be continued till only one pound has come over, supposing the water in the refrigeratory to have received 8° of heat; it is plain, that if the whole of the quantity thus received could be thrown into one pound of water, the latter would be heated to 800° ; which is sufficient to make an equal space of iron red-hot. But that this quantity of heat is received by the water in the refrigeratory has appeared from several experiments, which show that water, by being converted into vapour, absorbs between 800° and 900° of heat.

126
 Mr Watt's experiments on the evaporation of fluids in *vacuo*.
 On this principle we may explain some curious experiments made by Mr Watt with regard to the evaporation of fluids *in vacuo*. That gentleman had formed a design of converting water into steam with less expence of fuel, which he imagined might be done by removing the pressure of the air from the water, which he thought would thus require a much smaller quantity of fuel to convert it into vapour. Dr Black, however, perceiving that only the small quantity of sensible heat the steam possessed could thus be carried off, informed him beforehand that his project would not be found attended with the advantages he imagined. The experiment, however, was made in the following manner: A still was procured of tinned iron, the body of which resembled that of a retort, with a vessel serving as a condenser; the whole apparatus being close, excepting a little hole in the extremity of the condensing vessel. He first exhausted this vessel of air by holding the condenser over the retort, in which some boiling water was contained, until it was entirely converted into steam. He then suddenly stopped the little hole, and removed the vessels from the fire; when, after they were cooled, there was a pretty perfect vacuum formed by the condensation of the steam. The retort was then put on the fire, and turned so that the pipe and condensing vessel should

Vol. IV. Part I.

hang downward; and plunging them into cold water, heat was applied to the still till the water boiled, as could be known by the noise. It was kept boiling, till a quantity of steam was pushed over and condensed with a very gentle heat, the still feeling little warmer than his hand. After a certain quantity had been distilled, the apparatus was removed, and he had noted the heat of the water in the refrigeratory; but though the steam all along came over with so gentle a heat, he found the quantity communicated to the water in the refrigeratory to be surprisngly great, not less than 1000° ; so that it would have been more than sufficient to heat the quantity of liquor which came over red-hot.

127
 IV. Ignition, or the causing bodies to shine or emit light in the dark. This may be considered as a species of inflammation, and shall therefore be explained under that head: here we shall only observe, that ignition is a more steady and constant effect of heat than either the production of fluidity or vapour; and appears not only to be the same degree with regard to any particular body, but the same with regard to all kinds of matter. Dr Martin imagines, that a red-hot piece of iron is hotter than a red-hot piece of stone; but if you put into a crucible an hundred different kinds of matter, as metals, glasses, &c. that are capable of bearing a red heat, they will all begin to appear luminous about the same time, and their brightness will increase equally as their heat increases. But it is difficult to know at what point this begins, as we have no way of ascertaining the beginning or lowest degree of ignition but by the effect it produces on our sight, and we cannot be sure that we perceive the lowest degree of light; for we know that other animals see objects with such light as appears perfect darkness to us. Sir Isaac Newton's method of determining this has been already mentioned.

129
 Dr Boerhaave entertained a notion, that some metals, after being once brought into a state of fusion, could be made no hotter; and proposes the possibility of this as a question, "Whether the heat of metals can be increased after they are melted?" There is not, however, the least doubt but that their heat may be vastly increased after they are melted; and we know certainly that such as are of easy fusion may be heated to a vastly greater degree after being melted; and why may not those requiring stronger heats be the same? We are sure that this is the case with silver, which, after being melted, may be brought to such a heat as to become too dazzling for the eye to bear it. If Boerhaave's opinion were just, it would be impossible to cast any metal into moulds, because it must lose a little heat in being removed from the fire and in entering the mould; nor would they receive a proper impression if they did not contain a greater quantity of heat than was necessary for their fusion.

130
 Ignition appears to be universal; and all bodies capable of supporting it without being converted into an elastic vapour that cannot be confined, are affected the same way. Water, which in its ordinary state seems very little capable of enduring this heat, may be confined in strong vessels so as to become capable of melting lead, which is more than half way betwixt a red heat and that of boiling water. Experiments with the eolipile show also that it can be made red-hot; for when the steam passes through burning fuel, it can-

3 D

not

General
Effects of
Heat.

not miss of being made red-hot. Dr Black has also frequently seen the vapour of water heated by throwing it into the ash-pit of a furnace, so as to produce a very large and transparent flame in rising up through the vent. There is reason therefore to conclude, that ignition is one of the more general effects of heat, only that some bodies are incapable of it until they be reduced to a state of vapour.

132
Difference
betwixt ig-
nition and
inflammati-
on.

V. The last of the effects of heat here to be taken notice of is *inflammation*. It differs from ignition in this, that the bodies subject to the latter gradually grow cooler as soon as they are taken out of the fire, without undergoing any considerable change; while those subject to inflammation become continually hotter and hotter, communicating a vast quantity of heat to others, and undergoing a kind of decomposition themselves, insomuch, that by this means they have been thought to be reduced to their constituent principles or elements. Some substances indeed seem to be an exception to this, as in the open air they burn totally away, without leaving any residuum or producing any foot. These are spirit of wine, sulphur, and especially inflammable air; which last, by a proper mixture with dephlogisticated air, may be so totally consumed, that scarce a fiftieth part of the two will remain. On a careful examination of these substances, however, we find that there is by no means a total consumption, or indeed, properly speaking, any consumption at all, at least if we measure the quantity of matter by the weight of the substance employed. Thus, if we are at pains

to collect the vapour of burning spirit of wine, we will find, that an aqueous dew is collected, which sometimes equals the spirit of wine itself in weight. With regard to sulphur, the case is still more evident; for the vapour of this, when collected, not only equals but greatly exceeds the weight of the sulphur employed; and on burning dephlogisticated and inflammable air together, as much water is found to be produced as nearly equals the weight of both airs. In like manner, when we collect the ashes, water, foot, and oil, procured by burning any of the common inflammable substances, we will find, that they in general exceed the weight of the matter employed. The great waste of bodies by fire, therefore, is owing to the dissipation of the volatile principles they contain, which are carried off and rendered invisible by being mixed with the atmosphere.

The process of inflammation has long been explained from the presence of a substance called *Phlogiston* in those bodies which are subject to it, and which is supposed to be the same in all bodies belonging to this class; the differences between them arising from the principles with which it is combined. This doctrine, which was first introduced by Stahl, has given occasion to such various and discordant theories, that the existence of phlogiston has been lately denied altogether by M. Lavoisier, who brought in a new method of solving the phenomena of fire, heat, and ignition, without any assistance from this principle.

The foundation of M. Lavoisier's doctrine is the increase of weight in metals by calcination. This increase he finds to be precisely, or very nearly so, proportionable to the decrease of weight in the air in which they are calcined. His theory, therefore, is, that in the act of calcination, the pure part of the air,

which he calls the *acidifying* or *oxygenous* principle, unites with the metal, and converts it into a calx. In like manner, in substances truly inflammable, the heat and flame are supposed to proceed from the union of the pure air, or the oxygenous principle, with the substance, and converting it into those principles which are found to remain after inflammation. Thus the increased weight of the substance is easily accounted for; while the inflammation, in his opinion, is nothing more than a combination of the inflammable body itself with pure air, which has an attraction for it: and in confirmation of this it is urged, that when combustion is performed in empyreal or dephlogisticated air, the whole of the latter is absorbed; but in common atmospherical air only one fourth, being the quantity of pure air contained in it.

Other arguments in favour of this opinion are, that the calces of the perfect metals may be reduced without addition by the mere emission of the oxygenous principle, (dephlogisticated air); by an union with which they assume the form of a calx. Thus he evades a very strong argument used by the opposite party; who adduced, as a proof of the existence of phlogiston, the use of charcoal in the reduction of metals to their proper form. A dispute indeed took place betwixt M. Lavoisier and Dr Priestley concerning the reduction of the whole of a mercurial calx formed by an union with the nitrous acid without addition; the Doctor maintaining, that the whole could not be reduced by mere heat, but that a very perceptible quantity was always lost: but on a thorough examination of the subject, the truth seemed rather to lie on M. Lavoisier's side. See AEROLOGY.

Another theory, somewhat similar to that of Lavoisier's, has been published by Dr Lubbock, in an Inaugural Dissertation in 1784. In this he supposes two kinds of matter to exist in the universe; one he calls the *principium proprium*, the other the *principium forbile*; and it is this latter, which, according to our author, is the principle of mutability, or which, by being united in various proportions with the other, forms bodies of all the different kinds we see in nature. It is this principle, therefore, which he supposes to be absorbed in the calcination of metals, and not empyreal air, as M. Lavoisier supposes; and he contends, that this same principle extends throughout the whole system of nature, even to the utmost celestial bounds.

It would exceed the limits of this treatise to give an account of the various theories which have been invented, and the arguments used for and against them; nor indeed is there any occasion for doing so, as late experiments have reduced the dispute into a much narrower compass than before, and furnished the most decisive arguments in favour of the existence, of phlogiston.

The greatest objection to the belief of this principle was, that it could neither be seen nor felt by our senses directly, nor discover itself indirectly by the weight it communicated to the bodies with which it was united; on the contrary, the latter always became lighter in proportion to the quantity they contained: and so that it was imagined, instead of being possessed of any specific gravity of its own, to be a principle of positive levity, such as that of heat or light may be reasonably supposed. This objection, however, is now entirely removed; and phlogiston in the abstract is found

found to be no subtle principle capable of eluding our researches, but one very common, and easily met with, being no other than common charcoal. In the last edition of this work, under the article PHLOGISTON, it was shown, that inflammable air, deprived of its elasticity, and combined with metallic substances, is really their phlogiston; and that in the inflammable bodies commonly used, what we call their phlogiston, is really their oil; and that which exists in charcoal, and cannot be driven off by distillation, is part of the empyreumatic or burnt oil of the subject which adheres so obstinately. A similar doctrine soon after appeared in the Philosophical Transactions for 1782, and the identity of phlogiston and inflammable air was clearly proved by Mr Kirwan. Still, however, it was insisted by the French philosophers and others, that no *facts* had been adduced against M. Lavoisier, nor any decisive proofs appeared of the existence of phlogiston as a substance *per se*. Facts of this kind, however, have now been discovered by Dr Priestley, and are related under the articles AEROLOGY, CHARCOAL, PHLOGISTON, &c. It is sufficient at present to mention, that he has been able to convert the purest spirit of wine, and one of the hardest metals, viz. copper, as well as several others, into a substance entirely resembling charcoal; that by means of the heat of a burning glass in vacuo, he has dissipated this metallic charcoal, as well as the common kind, *entirely* into inflammable air, with the assistance only of a little water, which seems necessary to make it assume the aerial form, and perhaps is the true solvent of it; and by a combination with the element of heat, with the aid of the charcoal, is enabled to resist condensation in the common way*. This inflammable air, when absorbed by metallic calces, again reduces them to their metallic form: so that here is one fact by which the phlogiston not only appears to our senses, but we are able to ascertain its quantity with the utmost precision. Nor can it here be any objection, that the reduced metal is lighter than the calx; for this only proves that the metallic earth, while a calx, is united to a heavy ingredient (the basis of dephlogistified air), and in the latter to a light one, viz. charcoal, the basis of inflammable air. Another case in which the existence of phlogiston is made equally evident to our senses, and where no such objection can occur, is related under the article AEROLOGY, n° 112. It is there shown, that "by the loss of one grain of charcoal of copper (formed by the union of spirit of wine with the metal), and which like common charcoal was consumed without having any residuum, he reduced four ounce-measures of dephlogistified air till only one-ninth remained unabsorbed by water; and, again, with the loss of one grain and a half of charcoal, six and an half measures of dephlogistified air were reduced till five and an half measures were pure fixed air."—Here, then, is an absolute and undeniable evidence, that fixed air is composed of dephlogistified air, and charcoal or phlogiston, and elementary fire. There were no other ingredients present, and the charcoal must either have been annihilated or disposed of in the manner just mentioned: but the superior weight of the fixed air evidently shows that some ingredient had been added to the dephlogistified air; and which increase was more than we can

suppose to arise from the condensation of the dephlogistified air during the operation, for this sometimes amounted to no more than one-thirtieth part.

The strongest objection which can be made against the doctrine of phlogiston may be drawn from the total consumption of pure air in certain cases of combustion, for instance, in that of phosphorus, inflammable air, and iron. It must be observed, however, that in no case whatever is the air totally consumed; and in that of inflammable air water is produced by the union of the basis of the latter, that is charcoal, with the basis of dephlogistified air, the oxygenous principle of M. Lavoisier, and which appears to be one of the component parts of WATER. In the case of phosphorus, the latter is converted into an acid; and in all probability a quantity of water is also produced, by which part of it is converted into crystalline flowers. The case of the iron, therefore, alone remains to be considered. Dr Priestley's experiments on this subject are related at length under the article AEROLOGY, n° 67 *et seq.* In them the iron burnt briskly in dephlogistified air, which, according to the common theory, should have indicated the expulsion of a great quantity of phlogiston; yet the whole residuum, of which the fixed air, produced by the supposed union of the phlogiston or principle of inflammability, was only a part, scarce amounted sometimes to one-fourteenth of the air originally employed.

This argument, however, instead of contradicting the existence of phlogiston, only shows, that in some cases the dissipation of a very small quantity of phlogiston is necessary to inflammation; or that the aerial principle may combine with the iron in its metallic state. In this case only a very little quantity of the phlogiston of the iron was dissipated; for it was not reduced to a calx, but to that kind of scoria which flies off in scales by beating the metal when red-hot with an hammer. A decisive proof of this was had by uniting iron thus combined with the basis of dephlogistified air with inflammable air. By this the metal was indeed reduced to perfect iron again; but water was produced at the same time from the union of the basis of the two airs, that of the inflammable air being capable of furnishing a superfluous quantity, which united with the other into the form of a fluid.

The existence of phlogiston being thus proved, and its nature ascertained, we may now proceed to determine the question, Whether the great quantity of heat produced by the combustion of inflammable bodies proceeds from the bodies themselves, or from the air which must be admitted to them in order to make them burn? That the heat in this case proceeds from the atmosphere is evident; because in all cases of combustion there is a certain diminution undoubtedly takes place by means of the conversion of the dephlogistified part of the atmosphere into fixed air. It is proved, under the article *ELASTIC Vapours*, that elementary fire is the universal cause of elasticity in fluids. By uniting a certain quantity of it with any substance, the latter at length assumes an aerial or vaporous form; and it is this vapour alone which is inflammable*. Different vapours no doubt contain different quantities of these ingredients; but in all cases the basis of the dephlogistified part of the atmosphere

General Effects of Heat.

118 Heat the cause of the softness of bodies approaching to fluidity.

119 Absorption of heat the universal cause of fluidity.

120 Vapour formed by the absorption of latent heat.

121 Experiments by Dr Black on the conversion of water into vapour.

a fluid to a solid state, but to such as are in a kind of middle state betwixt solidity and fluidity; for every degree of softness depends on a certain degree of heat contained in the body. Thus, for instance, melted wax, allowed to cool slowly, soon becomes opaque and consistent; but it must be colder still before it attains its utmost degree of hardness. There is therefore a certain degree of heat below which every body is solid, and above which every one is fluid; the former being called the *congealing*, and the latter the *melting*, point of bodies.

By making experiments upon different substances, the Doctor was convinced that latent heat is the universal cause of fluidity; and the doctrine holds good in all the experiments that have hitherto been made upon spermaceti, bees-wax, and some of the metals. If they are melted, allowed to cool slowly, and a thermometer be immersed into them, we find, that as long as they continue fluid, their sensible heat diminishes very fast; but as soon as they begin to grow solid, the sensible heat continues greater than that of the air to which they are exposed; and during all this time it is communicating heat to the air, without having its sensible heat diminished: for the latent heat within the fluid gradually receives a sensible form, and keeps up the temperature, proving a source of sensible heat, which is communicated to the neighbouring bodies as well as the surrounding air. The softness and ductility of bodies depend on this also.

III. *Evaporation*. A third effect of the action of heat is that of converting bodies into vapour, by which they are rendered specifically lighter than the surrounding atmosphere, and enabled to rise in it. To account for this, many theories have been invented; but that of Dr Black, who accounts for it, as well as fluidity from the absorption of latent heat, is now universally received. The circumstances by which he proves and illustrates his doctrine are the following:

1. When we attend to the phenomena of boiling water, in a tea-kettle for instance, it may, when first put upon the fire, be about the temperature of 48° or 50° . In a quarter of an hour it will become heated to 212° . It then begins to boil, and has gained 162° of vapour in that time. Now, if the conversion of it into vapour depended on the quantity of sensible heat introduced, we may ask how long it will be necessary to raise it all in vapour? Surely another quarter of an hour should be sufficient; but this is far from being the case. Dr Black made some experiments upon this subject in conjunction with another gentleman. Having the opportunity of what is called a kitchen-table or a thick plate of cast iron, one end of which was made sensibly red-hot, they set upon this some iron vessels with circular flat bottoms, of about four inches diameter, and which contained a quantity of water. The temperature of the water was noted, as also when it began to boil; and when the whole of it was boiled away, it was found, that when set on the table its temperature had been 54° ; in four minutes it began to boil, and in that space of time received 158° degrees of heat. Had the evaporation, therefore, depended merely on the quantity of sensible heat introduced, it ought to have been dissipated entirely in a single minute more. It was, however, 18 minutes in dissipating; and therefore had received 807 degrees of heat before it was all evapo-

N^o 70.

rated. All this time, therefore, while the water continued to boil, it was receiving a great quantity of heat, which must have been flowing equally fast out of it; for the vessel was no hotter, and the iron plate continued equally hot, the whole time. The vessels were of different shapes, some of them cylindrical, some conical, others widening upwards; one of the designs of the experiment being to show how far the evaporation was retarded by the particular form of the vessels. By suspending a thermometer in the mouth of one of the evaporating vessels, the heat of the steam was found to be exactly 212° ; so that as the great quantity of heat absorbed was found neither to have remained in the water, nor to have been carried away by the steam in a sensible manner, we have nothing left to suppose, but that it flew off as one of the component parts of the steam in a latent state.

2. In an experiment to show the fixedness of the boiling point of water, Dr Black inclosed some of that fluid in a strong vial having a thermometer in it, and stopped close with a cork. By the application of heat he hoped now to be able to raise the thermometer some degrees above the boiling point, which would be the natural consequence of the confinement of the steam. When this was done, he pulled out the cork, and supposed that the water would now all fly out in vapour; but in this he was totally disappointed; a sudden and very tumultuous boiling ensued, which threw out some of the water; but though some quantity of steam likewise issued, the quantity of water was not considerably diminished. The vial had been heated to 20° above the boiling point, but almost instantly cooled down to 212° , when the cork was taken out.

3. Mr Watt, in making some experiments on the force of steam, had occasion to use Papin's digester, with a pipe proceeding from its side; the orifice of which was shut with a valve pressed down by one end of a lever. Thus he heated steam to 400° of Fahrenheit; after which, having suddenly struck off the lever, a quantity of steam flew out with considerable noise, and with such violence as to make an impression on the ceiling of the room; but this noise gradually diminished, and after ten minutes ceased entirely; and upon opening the machine, he found the greatest part of the water still remaining.

4. The change of sensible into latent heat in the formation of vapour, appears still more evident in the boiling of water *in vacuo*. Mr Boyle took a quantity of water which had been previously boiled to purge it of its air, and put it whilst hot under the receiver of an air-pump. In consequence of this it began again to boil, and continued boiling till it was only lukewarm, and it soon arrived at this temperature; so that in this case also the heat had disappeared during the conversion of the fluid into vapour. Others have repeated the experiment, as Boerhaave, Muschenbroek; and Robinson, who lectures on chemistry in Glasgow, says that the heat diminishes very fast till it comes to 90° or 95° , which seems to be the boiling point of water *in vacuo*. As a considerable part of the heat thus disappears, and is to be discovered neither in the water nor in the vapour, we must conclude that it enters the latter as part of its composition.

5. Thus also we may understand some curious experiments made by Dr Cullen upon ether and other volatile

General Effects of Heat.

122 Boiling point of water in *vacuo* determined by Mr Boyle.

123 And by Mr Robinson of Glasgow.

 volatile fluids. He employed some persons to make experiments upon the cold produced by evaporation; and willing to repeat them himself *in vacuo*, he put some of the most volatile liquors under the receiver

Dr Cullen's experiments on cold produced by evaporation. 124
 of an air-pump. One of these was ether. It was contained in a glass, in which there was also placed some water. When the air was extracted, the ether began to boil, and to be converted into vapour, till it became so very cold that it froze the water contained in the vessel, though the temperature of the room was about 50° . Here therefore there was a quantity of heat which disappeared all of a sudden; which it is plain could not be owing to its having any communication with that of the atmosphere or other cold bodies, as they could not render it colder than they were themselves. Ether therefore is to be considered as a fluid so volatile, that were it not for the pressure of the atmosphere it would be perpetually in the state of vapour.

Heat expelled in great quantity by the condensation of vapour. 125
 6. That this heat which enters into the vapour is not destroyed, but remains in a latent state, is easily proved; for we find that a great quantity of heat is expelled from vapour when it is condensed again to form the body it composed originally. This is easily ascertained by observing the quantity of heat communicated to the water in the refrigeratory of a still by any given quantity of liquid which comes over. Thus, if the refrigeratory contain 100 pounds of water, and the distillation be continued till only one pound has come over, supposing the water in the refrigeratory to have received 8° of heat; it is plain, that if the whole of the quantity thus received could be thrown into one pound of water, the latter would be heated to 800° ; which is sufficient to make an equal space of iron red-hot. But that this quantity of heat is received by the water in the refrigeratory has appeared from several experiments, which show that water, by being converted into vapour, absorbs between 800° and 900° of heat.

Mr Watt's experiments on the evaporation of fluids in *vacuo*. 126
 On this principle we may explain some curious experiments made by Mr Watt with regard to the evaporation of fluids *in vacuo*. That gentleman had formed a design of converting water into steam with less expence of fuel, which he imagined might be done by removing the pressure of the air from the water, which he thought would thus require a much smaller quantity of fuel to convert it into vapour. Dr Black, however, perceiving that only the small quantity of sensible heat the steam possessed could thus be carried off, informed him beforehand that his project would not be found attended with the advantages he imagined. The experiment, however, was made in the following manner: A still was procured of tinned iron, the body of which resembled that of a retort, with a vessel serving as a condenser; the whole apparatus being close, excepting a little hole in the extremity of the condensing vessel. He first exhausted this vessel of air by holding the condenser over the retort, in which some boiling water was contained, until it was entirely converted into steam. He then suddenly stopped the little hole, and removed the vessels from the fire; when, after they were cooled, there was a pretty perfect vacuum formed by the condensation of the steam. The retort was then put on the fire, and turned so that the pipe and condensing vessel should

hang downward; and plunging them into cold water, heat was applied to the still till the water boiled, as could be known by the noise. It was kept boiling, till a quantity of steam was pushed over and condensed with a very gentle heat, the still feeling little warmer than his hand. After a certain quantity had been distilled, the apparatus was removed, and he had noted the heat of the water in the refrigeratory; but though the steam all along came over with so gentle a heat, he found the quantity communicated to the water in the refrigeratory to be surprisngly great, not less than 1000° ; so that it would have been more than sufficient to heat the quantity of liquor which came over red-hot.

IV. Ignition, or the causing bodies to shine or emit light in the dark. This may be considered as a species of inflammation, and shall therefore be explained under that head: here we shall only observe, that ignition is a more steady and constant effect of heat than either the production of fluidity or vapour; and appears not only to be the same degree with regard to any particular body, but the same with regard to all kinds of matter. Dr Martin imagines, that a red-hot piece of iron is hotter than a red-hot piece of stone; but if you put into a crucible an hundred different kinds of matter, as metals, glasses, &c. that are capable of bearing a red heat, they will all begin to appear luminous about the same time, and their brightness will increase equally as their heat increases. But it is difficult to know at what point this begins, as we have no way of ascertaining the beginning or lowest degree of ignition but by the effect it produces on our sight, and we cannot be sure that we perceive the lowest degree of light; for we know that other animals see objects with such light as appears perfect darkness to us. Sir Isaac Newton's method of determining this has been already mentioned.

Dr Boerhaave entertained a notion, that some metals, after being once brought into a state of fusion, could be made no hotter; and proposes the possibility of this as a question, "Whether the heat of metals can be increased after they are melted?" There is not, however, the least doubt but that their heat may be vastly increased after they are melted; and we know certainly that such as are of easy fusion may be heated to a vastly greater degree after being melted; and why may not those requiring stronger heats be the same? We are sure that this is the case with silver, which, after being melted, may be brought to such a heat as to become too dazzling for the eye to bear it. If Boerhaave's opinion were just, it would be impossible to cast any metal into moulds, because it must lose a little heat in being removed from the fire and in entering the mould; nor would they receive a proper impression if they did not contain a greater quantity of heat than was necessary for their fusion.

Ignition appears to be universal; and all bodies capable of supporting it without being converted into an elastic vapour that cannot be confined, are affected the same way. Water, which in its ordinary state seems very little capable of enduring this heat, may be confined in strong vessels so as to become capable of melting lead, which is more than half way betwixt a red heat and that of boiling water. Experiments with the eolipile show also that it can be made red-hot; for when the steam passes through burning fuel, it can-

General
Effects of
Heat.

not miss of being made red-hot. Dr Black has also frequently seen the vapour of water heated by throwing it into the ash-pit of a furnace, so as to produce a very large and transparent flame in rising up through the vent. There is reason therefore to conclude, that ignition is one of the more general effects of heat, only that some bodies are incapable of it until they be reduced to a state of vapour.

132
Difference
betwixt ig-
nition and
inflammation.

V. The last of the effects of heat here to be taken notice of is *inflammation*. It differs from ignition in this, that the bodies subject to the latter gradually grow cooler as soon as they are taken out of the fire, without undergoing any considerable change; while those subject to inflammation become continually hotter and hotter, communicating a vast quantity of heat to others, and undergoing a kind of decomposition themselves, insomuch, that by this means they have been thought to be reduced to their constituent principles or elements. Some substances indeed seem to be an exception to this, as in the open air they burn totally away, without leaving any residuum or producing any foot.

133
Inflammation decom-
pounds but
does not de-
stroy bodies

These are spirit of wine, sulphur, and especially inflammable air; which last, by a proper mixture with dephlogisticated air, may be so totally consumed, that scarce a fiftieth part of the two will remain. On a careful examination of these substances, however, we find that there is by no means a total consumption, or indeed, properly speaking, any consumption at all, at least if we measure the quantity of matter by the weight of the substance employed. Thus, if we are at pains to collect the vapour of burning spirit of wine, we will find, that an aqueous dew is collected, which sometimes equals the spirit of wine itself in weight. With regard to sulphur, the case is still more evident; for the vapour of this, when collected, not only equals but greatly exceeds the weight of the sulphur employed; and on burning dephlogisticated and inflammable air together, as much water is found to be produced as nearly equals the weight of both airs. In like manner, when we collect the ashes, water, foot, and oil, procured by burning any of the common inflammable substances, we will find, that they in general exceed the weight of the matter employed. The great waste of bodies by fire, therefore, is owing to the dissipation of the volatile principles they contain, which are carried off and rendered invisible by being mixed with the atmosphere.

136
Of the ex-
istence of
phlogiston.

The process of inflammation has long been explained from the presence of a substance called *Phlogiston* in those bodies which are subject to it, and which is supposed to be the same in all bodies belonging to this class; the differences between them arising from the principles with which it is combined. This doctrine, which was first introduced by Stahl, has given occasion to such various and discordant theories, that the existence of phlogiston has been lately denied altogether by M. Lavoisier, who brought in a new method of solving the phenomena of fire, heat, and ignition, without any assistance from this principle.

137
Denied by
M. Lavoisier.

138
Arguments
against it
drawn from
the increas-
ed weight
of metals
by calcina-
tion.

The foundation of M. Lavoisier's doctrine is the increase of weight in metals by calcination. This increase he finds to be precisely, or very nearly so, proportionable to the decrease of weight in the air in which they are calcined. His theory, therefore, is, that in the act of calcination, the pure part of the air,

which he calls the *acidifying* or *oxygenous* principle, unites with the metal, and converts it into a calx. In like manner, in substances truly inflammable, the heat and flame are supposed to proceed from the union of the pure air, or the oxygenous principle, with the substance, and converting it into those principles which are found to remain after inflammation. Thus the increased weight of the substance is easily accounted for; while the inflammation, in his opinion, is nothing more than a combination of the inflammable body itself with pure air, which has an attraction for it: and in confirmation of this it is urged, that when combustion is performed in empyreal or dephlogisticated air, the whole of the latter is absorbed; but in common atmospherical air only one fourth, being the quantity of pure air contained in it.

Other arguments in favour of this opinion are, that the calces of the perfect metals may be reduced without addition by the mere emission of the oxygenous principle, (dephlogisticated air); by an union with which they assume the form of a calx. Thus he evades a very strong argument used by the opposite party; who adduced, as a proof of the existence of phlogiston, the use of charcoal in the reduction of metals to their proper form. A dispute indeed took place betwixt M. Lavoisier and Dr Priestley concerning the reduction of the whole of a mercurial calx formed by an union with the nitrous acid without addition; the Doctor maintaining, that the whole could not be reduced by mere heat, but that a very perceptible quantity was always lost: but on a thorough examination of the subject, the truth seemed rather to lie on M. Lavoisier's side. See AEROLOGY.

Another theory, somewhat similar to that of Lavoisier's, has been published by Dr Lubbock, in an Inaugural Dissertation in 1784. In this he supposes two kinds of matter to exist in the universe; one he calls the *principium proprium*, the other the *principium forbile*; and it is this latter, which, according to our author, is the principle of mutability, or which, by being united in various proportions with the other, forms bodies of all the different kinds we see in nature. It is this principle, therefore, which he supposes to be absorbed in the calcination of metals, and not empyreal air, as M. Lavoisier supposes; and he contends, that this same principle extends throughout the whole system of nature, even to the utmost celestial bounds.

It would exceed the limits of this treatise to give an account of the various theories which have been invented, and the arguments used for and against them; nor indeed is there any occasion for doing so, as late experiments have reduced the dispute into a much narrower compass than before, and furnished the most decisive arguments in favour of the existence, of phlogiston.

The greatest objection to the belief of this principle was, that it could neither be seen nor felt by our senses directly, nor discover itself indirectly by the weight it communicated to the bodies with which it was united; on the contrary, the latter always became lighter in proportion to the quantity they contained; so that it was imagined, instead of being possessed of any specific gravity of its own, to be a principle of positive levity, such as that of heat or light may be reasonably supposed. This objection, however, is now entirely removed; and phlogiston in the abstract is found

found to be no subtle principle capable of eluding our researches, but one very common, and easily met with, being no other than common charcoal. In the last edition of this work, under the article PHLOGISTON, it was shown, that inflammable air, deprived of its elasticity, and combined with metallic substances, is really their phlogiston; and that in the inflammable bodies commonly used, what we call their phlogiston, is really their oil; and that which exists in charcoal, and cannot be driven off by distillation, is part of the empyreumatic or burnt oil of the subject which adheres so obstinately. A similar doctrine soon after appeared in the Philosophical Transactions for 1782, and the identity of phlogiston and inflammable air was clearly proved by Mr Kirwan. Still, however, it was insisted by the French philosophers and others, that no *facts* had been adduced against M. Lavoisier, nor any decisive proofs appeared of the existence of phlogiston as a substance *per se*. Facts of this kind, however, have now been discovered by Dr Priestley, and are related under the articles AEROLOGY, CHARCOAL, PHLOGISTON, &c. It is sufficient at present to mention, that he has been able to convert the purest spirit of wine, and one of the hardest metals, viz. copper, as well as several others, into a substance entirely resembling charcoal; that by means of the heat of a burning glass in vacuo, he has dissipated this metallic charcoal, as well as the common kind, *entirely* into inflammable air, with the assistance only of a little water, which seems necessary to make it assume the aerial form, and perhaps is the true solvent of it; and by a combination with the element of heat, with the aid of the charcoal, is enabled to resist condensation in the common way*. This inflammable air, when absorbed by metallic calces, again reduces them to their metallic form: so that here is one fact by which the phlogiston not only appears to our senses, but we are able to ascertain its quantity with the utmost precision. Nor can it here be any objection, that the reduced metal is lighter than the calx; for this only proves that the metallic earth, while a calx, is united to a heavy ingredient (the basis of dephlogisticated air), and in the latter to a light one, viz. charcoal, the basis of inflammable air.

Another case in which the existence of phlogiston is made equally evident to our senses, and where no such objection can occur, is related under the article AEROLOGY, n° 112. It is there shown, that "by the loss of one grain of charcoal of copper (formed by the union of spirit of wine with the metal), and which like common charcoal was consumed without having any residuum, he reduced four ounce-measures of dephlogisticated air till only one-ninth remained unabsorbed by water; and, again, with the loss of one grain and a half of charcoal, six and an half measures of dephlogisticated air were reduced till five and an half measures were pure fixed air."—Here, then, is an absolute and undeniable evidence, that fixed air is composed of dephlogisticated air, and charcoal or phlogiston, and elementary fire. There were no other ingredients present, and the charcoal must either have been annihilated or disposed of in the manner just mentioned: but the superior weight of the fixed air evidently shows that some ingredient had been added to the dephlogisticated air; and which increase was more than we can

suppose to arise from the condensation of the dephlogisticated air during the operation, for this sometimes amounted to no more than one-thirtieth part.

The strongest objection which can be made against the doctrine of phlogiston may be drawn from the total consumption of pure air in certain cases of combustion, for instance, in that of phosphorus, inflammable air, and iron. It must be observed, however, that in no case whatever is the air totally consumed; and in that of inflammable air water is produced by the union of the basis of the latter, that is charcoal, with the basis of dephlogisticated air, the oxygenous principle of M. Lavoisier, and which appears to be one of the component parts of WATER. In the case of phosphorus, the latter is converted into an acid; and in all probability a quantity of water is also produced, by which part of it is converted into crystalline flowers. The case of the iron, therefore, alone remains to be considered. Dr Priestley's experiments on this subject are related at length under the article AEROLOGY, n° 67 *et seq.* In them the iron burnt briskly in dephlogisticated air, which, according to the common theory, should have indicated the expulsion of a great quantity of phlogiston; yet the whole residuum, of which the fixed air, produced by the supposed union of the phlogiston or principle of inflammability, was only a part, scarce amounted sometimes to one-fourteenth of the air originally employed.

This argument, however, instead of contradicting the existence of phlogiston, only shows, that in some cases the dissipation of a very small quantity of phlogiston is necessary to inflammation; or that the aerial principle may combine with the iron in its metallic state. In this case only a very little quantity of the phlogiston of the iron was dissipated; for it was not reduced to a calx, but to that kind of scoriae which flies off in scales by beating the metal when red-hot with an hammer. A decisive proof of this was had by uniting iron thus combined with the basis of dephlogisticated air with inflammable air. By this the metal was indeed reduced to perfect iron again; but water was produced at the same time from the union of the basis of the two airs, that of the inflammable air being capable of furnishing a superfluous quantity, which united with the other into the form of a fluid.

The existence of phlogiston being thus proved, and its nature ascertained, we may now proceed to determine the question, Whether the great quantity of heat produced by the combustion of inflammable bodies proceeds from the bodies themselves, or from the air which must be admitted to them in order to make them burn? That the heat in this case proceeds from the atmosphere is evident; because in all cases of combustion there is a certain diminution undoubtedly takes place by means of the conversion of the dephlogisticated part of the atmosphere into fixed air. It is proved, under the article *ELASTIC Vapours*, that elementary fire is the universal cause of elasticity in fluids. By uniting a certain quantity of it with any substance, the latter at length assumes an aerial or vaporous form; and it is this vapour alone which is inflammable*. Different vapours no doubt contain different quantities of these ingredients; but in all cases the basis of the dephlogisticated part of the atmosphere

must unite with the phlogiston of the inflammable body, or with something else, so that a decomposition may ensue: and it is this decomposition which produces the heat and light; for then the fire contained in the atmosphere having no longer any thing to absorb it, must appear in its proper form. But in those cases where there is a great quantity of phlogiston, and consequently much fixed air produced, the latter absorbs so much heat in a latent state, that the quantity communicated to surrounding bodies must be greatly diminished; and if by an excess of this ingredient, not only fixed air, but the phlogisticated kind and gross smoke be also produced, this diminishes the heat still farther by the great absorption, and will even destroy it altogether. The remedy for this is either to diminish the quantity of phlogiston, or to augment the quantity of air; which, by furnishing a greater quantity of dephlogisticated basis, affords an opportunity for the evolution of a greater quantity of heat. On the other hand, when the quantity of air is too great, the phlogistic matter cannot combine with the basis of the pure air in sufficient quantity to effect a decomposition; and therefore the heat is absorbed in a latent state, and the fire goes out.

From this theory, which is further illustrated under the articles FIRE, FLAME, HEAT, PHLOGISTON, &c. we may not only have a rational idea of the manner in which inflammation is generally accomplished, but see why a fire may be put out both by too great a quantity of fuel, and by too great a quantity of air. We may also see why the solar beams and electric fluid, which contain no phlogistic matter, excite a much more powerful heat than any we can raise in our hottest furnaces. The difference between ignition and inflammation will now likewise appear; such bodies as are capable only of ignition containing little or no phlogiston, but inflammable bodies a great deal.

Elective
Attraction.

SECT. II. Of the Doctrine of Elective Attraction, and of the different Objects of Chemistry.

BEFORE we proceed to give a general theory of the changes which happen upon the mixtures of different bodies together, or exposing them singly to heat, we must observe, that all depend on certain qualities in bodies, by which some of them are apt to join together, and to remain united while they have an opportunity. The cause of these qualities is totally unknown; and therefore philosophers, after the example of Sir Isaac Newton, have expressed the apparent effect of this unknown cause by the word *attraction*. From them the word has been adopted by the chemists, and is now generally used in speaking of the phenomena which are observed in the mixture of different substances; but to distinguish it from other kinds, it is usually called *Elective*.

This attraction is not equally strong between all substances; in consequence of which, if any body is compounded of two others, and another is presented to it which has a greater attraction for one of the component parts than they have for one another, the substance will be *decomposed*. A new compound is then formed by the union of that third substance with one of the component parts or *elements* (if we please to call them so) of the first. If the attraction between the body superadded and either of the component parts of the other is not so strong as that between themselves, no decomposition will ensue; or if the third substance is attracted by both the others, a new composition will take place by the union of all the three.

The objects of chemistry, as we have already observed, are so various, that an enumeration of them all is impossible. To ease the mind, therefore, when speaking of them, and render more useful any thing that is said or wrote on chemistry, it is necessary to divide them into different classes, comprehending in each class those bodies which have the greatest resemblance to one another, and to which one common rule applies pretty generally.—The division formerly used, was that of vegetables, animals, and minerals; but this has been thought improper, as there are many substances in each of those kingdoms which differ very widely from one another, and which are by no means subject to the same laws. The most approved method,

163
Objects of
chemistry
how clas-
sed.

Salts. thod, at present, of arranging the objects of chemistry, is into salts, earths, metals, inflammable substances, waters, animal and vegetable substances.

SECT III. *Salts.*

164
Salts.

SALTS are either *fusible*, that is, capable of abiding the fire, and melting in a strong heat, without being dissipated; or *volatile*, that is, being dispersed in vapour with a small heat. Their other properties are; that they are soluble in water; not inflammable, unless by certain additions; and give a sensation of taste when applied to the tongue.

The most general characteristic of salts is, that they are all soluble in water, though some of them with much more difficulty than others. Most of them have likewise the property of forming themselves, in certain circumstances, into solid transparent masses of regular figures, different according to the different salt made use of, and which are termed *crystals* of that salt. In this state they always contain a quantity of water; and therefore the utmost degree of purity in which a salt can be procured, is when it has been well crystallized, and the crystals are freed of their superfluous moisture by a gentle heat. They generally appear then in the form of a white powder.

165
Phenomena attending their solution.

In the solution of salts in water, the first thing observable is, that the water parts with the air contained in it; which immediately rises to the top in the form of bubbles. This, however, is most remarkable when the salt is in the dry form we have just now mentioned, because there is always a quantity of air entangled among the interstices of the powder, which rises along with the rest; and this discharge of air is sometimes so great, as to be mistaken for an effervescence. From this, however, it is essentially different. See **EFFERVESCENCE**.

Another thing observable in the solution of salts is, that a considerable change happens in the temperature of the water in which they are dissolved; the mixture becoming either a good deal warmer or colder than either the salt or the water were before. In general, however, there is an increase of cold, and scarce any salt produces heat, except when it has been made very dry, and deprived of that moisture which it naturally requires; and thus the heating of salts by being mixed with water may be explained on the same principle with the heat produced by quicklime. See **QUICKLIME**.

After salt has been dissolved in a certain quantity by water, no more of that salt will be taken up unless the water is heated; and as long as the heat continues to increase, the salt will be dissolved. When the water boils, at which time it has attained its greatest heat, and will take up no more salt, it is then said to be *saturated* with that salt. This, however, does not prevent it from taking up a certain quantity of another salt, and after that perhaps of a third, or fourth, without letting go any of the first which it had dissolved. How far this property of water extends, has not yet been ascertained by experiments.

To the above rule there is only one exception known as yet; namely, common sea-salt: for water dissolves it in the very same quantity when cold as when boiling hot. It has been said by some, that all deliquescent salts, or those which grow moist on being

exposed to the air, had the same property: but this is found to be a mistake.

This property of solubility, which all the salts possess in common, renders them easily miscible together; and the property by which most of them shoot into crystals, renders those easily separable again which have no particular attraction for one another. This is likewise rendered still more easy by their requiring different proportions of water, and different degrees of heat, to suspend them; for by this they crystallize at different times, and we have not the trouble of picking the crystals of one out among those of the other.

The manner in which the solution of salts in water is effected, is equally unaccountable with most of the other operations of nature. Sir Isaac Newton supposed that the particles of water got between those of the salt, and arranged them all at an equal distance from one another: and from this he also accounts for the regular figures they assume on passing into a crystalline form; because, having been once arranged in an orderly manner, they could not come together in disorder, unless something was to disturb the water in which they were suspended; and if any such disturbance is given, we find the crystals are by no means so regular as otherwise they would have proved. Others have thought that these figures depend on a certain *polarity* in the very small particles into which the salt is resolved when in a state of solution. These things, however, are merely conjectural; neither is it a matter of any consequence to a chemist whether they are right or wrong.

Though solution is that operation which salts undergo the most easily, and which should seem to affect them the least of any, a repetition of it proves nevertheless very injurious to them, especially if it is followed by quick evaporation; and the salt, instead of being crystallized, is dried with a pretty strong heat. Newman relates, that a pound of sea-salt was reduced, by 13 solutions and exsiccations, to half an ounce; and even that was mostly earth. Where solution is required, therefore, it ought always to be done in close vessels, in which also the subsequent evaporation should be performed, (see **EVAPORATION**); and in all cases where crystallization is practicable, it ought to be preferred to violent exsiccation.

The two great divisions of salts are into acids and alkalies. The former of these are known by their peculiar taste, which is called *acid* or *sour*. They are not found in a solid form; neither are any of them, except the acids of vitriol, of tartar, of phosphorus, and of borax, capable of being reduced to solidity. The others, when highly concentrated, that is, brought to the utmost degree of strength of which they are capable, always become an invisible vapour, permanently elastic, until it comes in contact with water, or some other substance with which they are capable of uniting. For such acids the name of *salts* seems less proper, as we can scarcely say that a *vapour*, which is already much more fluid than water, can be *dissolved* in that element.

The acids are divided into the mineral, the vegetable, and the animal; expressing their different origin, or where they are most commonly to be found. The mineral acids are commonly reckoned three; the

Salts.

vitriolic, the nitrous, and the marine. To this the acid of borax ought to be added; but its weakness makes it much less taken notice of as an acid than the others. A Swedish chemist, however, Mr Scheele, hath lately added several others, which are afterwards taken notice of.

The vegetable kingdom affords only two distinct species of acids, at least without the assistance of some chemical operation. The one appears fluid, and when concentrated to the utmost degree becomes an invisible vapour. This is produced from fermented liquors, under the name of *vinegar*. An acid similar to this, and which is thought not to be essentially different from it, is extracted from most vegetables by distillation with a strong fire. The other is likewise a consequence of fermentation; and crusts on the bottom and sides of casks in which wine is put to depurate itself. In its crude state it is called *tartar*; and when afterwards purified, is called the *cream*, or crystals, of tartar. As for the various acids produced in the different chemical processes to be afterwards related, we forbear to mention them at present, it being justly suspected that some of them are artificial.

The animal acids, which have hitherto been discovered, are only two; the acid of ants, and that of urine, which is also the acid of phosphorus. The first of these is volatile; and consequently must be supposed a vapour when in its strongest state: the other is exceedingly fixed; and will rather melt into glass than rise in vapours. Besides these, it is said an acid is contained in blood, in wasps, bees, &c.: but no experiments have as yet been made on these to determine this matter with any degree of precision.

170
Alkalies.

The alkalies are of two kinds; fixed and volatile. The fixed kind are subdivided into two; the vegetable, and mineral or fossil alkali. The vegetable is so called, because it is procured from the ashes of burnt vegetables; the fossil, because it is found native in some places of the earth, and is the basis of sea-salt, which in some places is dug out of mines in vast quantity. They are called *fixed*, because they endure a very intense degree of heat without being dissipated in vapour, so as even to form a part of the composition of glass. The volatile alkali is generally obtained by distillation from animal substances. In its pure state this alkali is perfectly invisible; but affects the sense of smelling to such a degree, as not to be approached with safety.

171
Different
action of
alkalies and
acids.

The acids and alkalies are generally thought to be entirely opposite in their natures to one another. Some, however, imagine them to be extremely similar, and to be as it were parts of one substance violently taken from each other. Certain it is, that when separated, they appear as opposite to one another as heat and cold. Their opposite action indeed very much resembles that of heat and cold, even when applied to the tongue; for the alkali has a hot, bitter, burning taste, while the acid, if not considerably concentrated, always gives a sensation of coldness. In their action too upon animal substances, the alkali dissolves, and reduces the part to a mucilage; while the acid, if not very much concentrated, tends to preserve it uncorrupted.

172
Neutral
salts.

If an alkaline salt, and moderately strong acid in a liquid state, be mixed together, they will immediately

unite; and, provided the alkali has not been deprived of its fixed air, their union will be attended with a very considerable effervescence: (see AEROLOGY.) If the alkali has been deprived of air, no effervescence will ensue, but they will quietly mix together; but if a due proportion of each has been added, the liquor will neither have the properties of an acid nor an alkali, but will be what is called *neutral*. The bringing the liquor into this state, is called *saturating* the acid or alkali, or combining them to the point of saturation.

If the liquor after such a saturation be gently evaporated, a saline mass will be left, which is neither an acid nor an alkali, but a new compound formed by the union of the two, and which is called a *perfect neutral salt*. The epithet *perfect* is given it, to make a distinction between the salts formed by the union of an acid and an alkali, and those formed by the union of acids with earthy or metallic substances; for these will likewise unite with acids, and some of the compounds will crystallize into regular figures; but, because of their weaker union with these substances, the salts resulting from combinations of this kind are called *imperfect*.

All acids, the volatile sulphureous one excepted, change the blue infusions of vegetables, such as violets, to a red; and alkalies, as well as some of the imperfect neutrals, change them to green. This is the nicest test of an acid or alkali abounding in any substance, and seems the most proper method of determining whether a solution intended to be neutral really is so or not.

173
Vegetable
colours
changed by
acids and
alkalies.

Though between every acid and alkali there is a very strong attraction, yet this is far from being the same in all; neither is it the same between the same acid and alkali in different circumstances of the acid. When the acids are in a liquid state, and as free as possible of inflammable matter, between which and the nitrous and vitriolic acids there is a very strong attraction, the vitriolic will expel any of the rest from an alkaline basis, and take its place. Thus, if you combine the acid of sea-salt, or marine acid, to the point of saturation, with the fossil alkali, a neutral salt will be formed, which has every property of common salt: but, if you pour on a certain proportion of the vitriolic acid, the acid of sea-salt will immediately be expelled; and the liquor, upon being evaporated, will contain not the neutral salt formed by an union of the marine acid with the alkali, but another consisting of the vitriolic acid joined with that alkali, and which has quite different properties from the former.

174
Differences
in the de-
grees of at-
traction be-
tween acids
and alkalies.

When the acids and alkalies are applied to one another in a liquid state, the vitriolic acid always shows itself to be the most powerful; but when applied in a solid form, and urged with a violent heat, the case is very much altered. Thus, the acid of borax, commonly called *sal sedativus*, is so weak as to be disengaged from its basis by every acid applied in a liquid form, that of tartar alone excepted; but if even the vitriolic acid combined with an alkali be mixed with this weak acid, then exsiccated, and at last urged with a vehement fire, the vitriolic acid will be disengaged from its basis, and rise in vapours, leaving the weaker acid in possession of the alkali. The same thing happens on adding the phosphoric or urinous acid,

Salts.

acid, or the acid of arsenic, &c. to combinations of the vitriolic or other acids with alkaline salts.—When the acids are in a liquid state, therefore the most powerful is the vitriolic; next the nitrous; then the marine; then vinegar; acid of ants; and lastly the sal sedativus and tartar, which seem to be nearly equal in this respect.—If they are applied in a solid form, the most powerful are the sal sedativus and phosphorine acid; then the vitriolic, nitrous, marine, and vegetable acids.

When they are reduced to vapour, the case is exceedingly different; for then the marine acid appears to be the most powerful, and the vitriolic the least so of any. It is impossible, however, to preserve the vitriolic acid in the form of vapour, without combining it with a certain quantity of inflammable matter, which must necessarily destroy its strength. Dr Priestley found, that the marine acid, when reduced to vapour, was capable of disuniting the nitrous acid from a fixed alkali.

Though the vitriolic acid sometimes assumes a solid form, it is by no means easy to reduce it to this state by mere concentration, without the assistance of nitrous acid. Baldasart, however, pretends that he discovered, in the neighbourhood of a volcano, a pure and icy oil of vitriol, from which nothing could be precipitated by alkaline salts; though there is certainly very great reason to doubt the accuracy of this observation. Of late the nitrous acid has also been found capable of assuming a solid form. This was first observed by M. Bernhard in distilling a very large quantity of the acid. At that time he perceived a white salt adhering to the inside of the receiver, which on examination proved to be the acid of nitre in a concrete form; being extremely corrosive, emitting red vapours copiously on being exposed to the air, and at length totally evaporating in it. Its specific gravity, however, was far inferior to that of the glacial oil of vitriol.

175
Acids unite
with phlo-
giston.

The acids have the property of uniting themselves to many other substances besides fixed alkalies, and forming neutral compounds with them. Of these the chief is the principle of inflammability or phlogiston. In the vitriolic, nitrous, and phosphorine acids, the attraction for this principle is very strong; so great, that the two former will even leave a fixed alkali to unite with it. In the marine acid it is less perceptible; in the liquid vegetable or animal acid still less; and in the acid of tartar, and sal sedativus, not at all.

176
With me-
tals and
earth.

Besides this, all acids will dissolve metallic and earthy substances: with these, however, they do not in general unite so firmly with alkaline salts; nor do they unite so strongly with metals as with earths.

177
Electric
attractions

In general, therefore, we may expect, that after having dissolved a metal in any acid whatever, if we add an earthy substance to that solution, the acid will quit the metal, which it had before dissolved, to unite with the earth. In this case the solution will not be clear as before, but will remain muddy, and a quantity of powder will fall to the bottom. This powder is the metalline substance itself, but deprived of one of its component parts; and in this case it is said to *precipitate* in the form of a *calx*.

If to this new solution of the earthy substance in an acid liquor, a volatile alkaline salt, not deprived of its

fixed air, is added, the acid will quit the earth, and unite with the alkaline salt. The earth thus disengaged will again *precipitate*, and lie at the bottom in fine powder, while the volatile alkali and acid remain combined together, and the liquor again becomes clear.

The attraction between volatile alkalies and acids is considerably less than between fixed alkalies and the same acids. If, therefore, a fixed alkali be now added to the liquor, the volatile alkali will be separated, and the acid will unite with the fixed alkali. The volatile alkali indeed, being perfectly soluble in water, cannot precipitate, but will discover its separation by the pungent smell of the mixture; and upon evaporating the liquor, the volatile alkali will be dissipated, and a saline mass, consisting of the acid and fixed alkali, will remain.

Lastly, If the acid employed was the nitrous, which has a strong attraction for the principle of inflammability, if the saline mass be mixed with a proper quantity of inflammable matter, and exposed to a strong heat, the acid will leave the alkali with vast rapidity, combine with the inflammable matter, and be destroyed in flame in a moment, leaving the alkali quite pure.

Though the above-mentioned effects generally happen, yet we are not to expect that they will invariably prove the same whatever acid is made use of; or even that they will be the same in all possible variety of circumstances in which the same acid can be used.—The acid of tartar is one exception, where the general rule is in a manner reversed; for this acid will quit a fixed alkali for an earth, especially if calcined, and even for iron. If lead, mercury, or silver, are dissolved in the nitrous acid, and a small quantity of the marine acid is added, it will separate the stronger nitrous acid, and fall to the bottom with the metals in form of a white powder.—The vitriolic acid, by itself, has a greater attraction for earthy substances than for metals; and greater still for fixed alkaline salts than for either of these: but if quicksilver is dissolved in the nitrous acid, and this solution is poured into a combination of vitriolic acid with fixed alkali, the vitriolic acid will quit the alkali to unite with the quicksilver. Yet quicksilver by itself cannot easily be united with this acid. The reason of all these anomalies, however, is fully explained in the following section.

§ 1. Of the Operations of Solution and Precipitation.

THE chemical solution of solid bodies in acid or other menstrua, is a phenomenon which, though our familiarity with it has now taken off our surprise, must undoubtedly have occasioned the greatest admiration and astonishment in those who first observed it. It would far exceed the limits of this treatise to speak particularly of all the various circumstances attending the solution of different substances in every possible menstruum. The following are the most remarkable, collected from Mr Bergman's Dissertation on Metallic Precipitates.

1. On putting a small piece of metal into any acid, it is dissolved sometimes with violence, sometimes gently, according to the nature of the menstruum and of the metal to be dissolved.

2. The nitrous acid is the most powerful in its action.

Solution
and Preci-
pitation.

181

Nitrous acid
the most
violent in
its opera-
tion.

tion upon metallic substances, when unassisted by heat. So great indeed is the violence with which this acid sometimes acts, that the metal, instead of being dissolved, separates instantaneously from it in the form of a calx or powder scarce soluble in any menstruum, at the same time that the heat, effervescence, and noxious vapours issuing from the mixture, render it absolutely necessary to moderate the action of the menstruum, either by dilution or cold, or both. In other cases, however, as when put to gold or platina, the nitrous acid has no effect until it be united with the marine, when the mixture acts upon those metals, which neither of the acids singly would touch.

182

Vitriolic
acid acts
more weak-
ly.

3. The action of the vitriolic acid, though in the highest degree of concentration, is more weak. It does not readily attack silver or mercury unless assisted by a boiling heat, nor will even that be sufficient to make it act upon gold or platina.

183

Marine acid generally
more weak than
either, except when
dephlogistified.

4. The action of marine acid, unless on some particular substances, is still more weak; but when dephlogistified, or deprived of part of the phlogiston essential to its constitution as an acid, it acts much more powerfully, and dissolves all the metals completely.

184

The rest of
the acids
much
weaker still.

5. The other acids, as those of fluor, borax, with such as are obtained from the animal and vegetable kingdoms, are much inferior in their powers as solvents, unless in very few instances.

185

Different
degrees of
solubility in
metals.

6. Metals vary very much in their degrees of solubility; some yielding to almost every menstruum, and others, as has been already observed, being scarce acted upon by the most powerful.

186

Solution
sometimes
promoted
by abstract-
ing a cer-
tain pro-
portion of
phlogiston.

6. Zinc and iron are of the former kind, and gold and silver of the latter, eluding the marine; and gold, unless in one particular case, viz. when assisted by heat in a close vessel, the action of the nitrous acid also. These metals, however, which in their perfect state resist the action of the most powerful menstrea, may be dissolved much more readily when deprived of a certain quantity of their inflammable principle. But though the separation of this principle in some degree renders metals more soluble, the abstraction of too much of it, particularly in the case of iron and tin, renders these metals almost entirely insoluble. Manganese is the most remarkable instance of this power of the phlogistic principle, in depriving metals of their solubility by its absence, or restoring it to them by its presence; for this substance, when reduced to blackness, cannot be dissolved by any acid without the addition of some inflammable matter; but when by the addition of phlogiston it has become white, may be dissolved in any acid.

188

Solution of
metals at-
tended with
an effervescence.

7. The dissolution of metals by acids, even to their very last particle, is attended by a visible effervescence: this is more perceptible according to the quickness of the solution; but more obscure, and scarcely to be seen at all, when the solution proceeds slowly.

189

Various
kinds of e-
lastic fluids
extricated.

8. The elastic fluids extricated by these solutions are various, according to the nature of the acid and of the metal employed. With the nitrous, the fluid produced is commonly that called *nitrous air*; with vitriolic and marine acids the produce is sometimes inflammable air, sometimes otherwise, according to the nature of the metal acted upon.

9. Heat in a greater or smaller degree is always produced during the dissolution of metals; and the de-

No 70.

6

gree of it is in proportion to the quantity of the matter and the quickness of the solution; and hence, in small quantities of metal, and when the solution proceeds very slowly, the temperature of the mass is scarcely altered.

10. The calces of metals either yield no air at all, or only the aerial acid, unless when urged by a violent heat almost to ignition; when, by means of vitriolic or nitrous acid, they yield a quantity of pure air, after other elastic fluids, such as vitriolic, nitrous, or phlogisticated air. None of the dephlogisticated air is usually produced by the marine acid in conjunction with metallic calces.

11. The solutions of some metals are coloured, others are not. The colour of the former is only that which is proper to the calx, but rendered more vivid by the moisture. Thus solutions of gold and platina are yellow; those of copper, blue or green; solutions of nickel of a bright green; but those of cobalt are red, although the calx is black. We may observe that even this red colour may be heightened to blackness. Iron moderately calcined is green; but this rarely continues upon further dephlogistication. The white calces of silver, lead, tin, bismuth, arsenic, antimony, and manganese, are dissolved without colour; but solutions of lead, tin, and antimony, are somewhat yellow, unless sufficiently diluted. Mercury, however, forms a singular exception to this rule; for the orange-coloured calx of this metal forms a colourless solution. The metals yielding coloured solutions are gold, platina, copper, iron, tin, nickel, and cobalt; the rest, if properly depurated, give no tinge. A solution of silver is sometimes of a blue or green colour at first, although there be no copper present; the vitriolic acid becomes blue with copper; the nitrous may be made either blue or green at pleasure; the marine varies according to the quantity of water with which it is diluted. Manganese, when too much dephlogisticated, renders both the vitriolic and marine acids purple.

With regard to the cause of chemical solutions, our author observes, that though attraction must be looked upon as the fundamental cause, yet we may also lay it down as a maxim, that no metal can be taken up by an acid, and at the same time preserve the whole quantity of phlogiston which was necessary to it in its metallic state. A certain proportion of the principle of inflammability therefore may be considered as an obstacle which must be removed before a solution can take place. Thus, of all the acids, the nitrous attracts phlogiston the most powerfully, and separates it even from the vitriolic. A proof of this may be had by boiling sulphur slowly in concentrated nitrous acid. At length all its phlogiston may be separated, and the vitriolic acid will remain, deprived of its principle of inflammability. The extraordinary solvent powers of this acid, therefore, is conformed to the peculiarity of its nature in this respect. For this menstruum dissolves metals for solution with the greatest ease, most commonly without any assistance from external heat; which in some instances would be hurtful, by separating too much of phlogiston, as appears in the case of iron, tin, and antimony; all of which may be so far dephlogisticated by the nitrous acid, as to be rendered extremely difficult of solution: for this reason it is very often necessary, as has already been observed, to temper the

activity of this menstruum by water. The vitriolic acid requires a boiling heat before it can act upon silver or mercury. The reason of this is, that by means of the heat, the watery part of the menstruum is diminished, its power is thereby increased, and the connection of the metallic earths with the inflammable principle diminished. Marine acid, which contains phlogiston as one of its constituent principles, must necessarily have little or no effect on those metals which retain their principle of inflammability very obstinately. But its watery part being diminished by boiling, it assumes an aerial form, and powerfully attracts a larger quantity of phlogiston than before; so that in a vaporous state it will dissolve metals, particularly silver and mercury, which in its liquid form it would scarce be brought to touch. When dephlogisticated as much as possible, it attracts phlogiston with prodigious avidity, dissolving all metals by its attraction for their phlogiston, and, uniting the inflammable principle to itself, resumes the ordinary form of marine acid. When dephlogisticated by means of nitrous acid in aqua regis, it dissolves gold and platina. On the same principles may we account for its inferiority in power to the other acids.

It has already been observed that the metals differ much in their degrees of solubility, which is owing to the various degrees of force with which they retain their phlogiston. Those called perfect metals effectually resist calcination in the dry way. In this operation, the fire on the one hand, the great cause of the volatility of bodies, strenuously endeavours to expel the phlogiston; on the other hand, the basis of the dephlogisticated part of the atmosphere (the acidifying principle of M. Lavoisier, and the *principium forbile* of Dr Lubbock) attracts the calx strongly. Experience, however, shows, that these two forces united, cannot decompose gold, silver, or platina to any considerable degree. All the other metals yield to these forces when united, but not singly. Iron and zinc retain their inflammable principle so slightly, that any acid immediately acts upon them; but if the other metals be properly prepared for solution by being calcined to a certain degree, the acid will immediately take them up. Any further privation, however, would be injurious, and precipitate what was before dissolved. Thus the nitrous acid, when added to a solution of tin or antimony in marine acid, by its extraordinary attraction for phlogiston carries off such a quantity of it, that the calces of the metals are immediately precipitated.

The various elastic fluids which resemble air, and which are produced in plenty during the dissolution of metals, may be reduced to the following, viz. those excited by the vitriolic, nitrous, and marine acids, fluor acid, vinegar, alkaline salts, and hepar sulphuris.

Pure vitriolic acid exposed to a violent heat, is indeed resolved into vapours, but of such a nature, that when the heat is gone, they condense again into an acid liquor of the same nature as before. But if any substance be added which contains phlogiston in a separable state, an elastic fluid is produced by means of fire, which is scarcely condensable by the most extreme cold, unless it comes in contact with water. This is called the volatile sulphureous acid, or vitriolic acid air, which may be totally absorbed by water. In this case the bond of union betwixt it and the phlogiston

is so weak, that the latter soon flies off totally, and common vitriolic acid is regenerated.

The nitrous acid undergoes a similar change in a more obvious manner. Let a piece of silver, for instance, be put into a dilute nitrous acid, and the surface of the metal will instantly be covered with innumerable bubbles, which arising to the top of the liquor, there burst; and if collected, are found to be nitrous air. The nitrous acid saturates itself with phlogiston more completely than the vitriolic; therefore the elastic fluid produced, or nitrous air, does not unite with water, and scarce retains any vestige of an acid nature. The vitriolic acid, however, differs from the nitrous in this respect, that the phlogiston is absorbed by the latter even beyond the point necessary to obliterate its acid nature. In proof of this, our author adduces the decomposition of hepatic by means of nitrous air.

The marine acid exhibits different phenomena. It naturally contains phlogiston, and therefore can by its means be resolved into a kind of air somewhat similar to that produced by the vitriolic acid when artificially united to the same principle, and which has the same property, viz. that of remaining permanently elastic as long as it is kept from the contact of water. But as the acid we speak of naturally contains phlogiston, there is no necessity of adding more to produce this effect. In the mean time, the marine as well as nitrous air, when in its expanded state, attracts phlogiston, and that with wonderful avidity.

When the marine acid is dephlogisticated, it yields another elastic fluid of a reddish brown colour, having an odour like that of warm aqua regia. This does not unite with water, or only in very small quantity; and by the addition of a proper proportion of phlogiston may be reduced again to common marine acid. It is said that the marine acid may be dephlogisticated by lead as well as by manganese, the nitrous acid, and arsenic.

The fluor acid abounds with phlogiston, and therefore may, without any adventitious matter, be reduced to an elastic fluid. This air is easily distinguished from all others by its corrosion of glass whilst hot.

Vinegar also contains phlogiston; and for that reason, when well dephlegmated, may be reduced without addition into a permanently elastic fluid, called acetous air.

All these fluids seem to be nothing else, according to Mr Bergman, than the acids themselves expanded by phlogiston. "Perhaps (says he) the matter of heat also enters their composition." The experiments lately made on these subjects, however, have put it beyond all doubt, that the expansive principle is not phlogiston but heat; nevertheless, it seems highly probable, that these elastic fluids do really consist of the acid united to phlogiston, and expanded by heat. This is also the case with the caustic volatile alkali, now called alkaline air.

In the hepatic air, it has been shown by Mr Bergman, that sulphur exists which contains phlogiston; and there is little reason to doubt that the expansive power here is the same as in other cases. See HEPATIC AIR.

The heat generated during the solution of metals is by Mr Bergman supposed to be owing to the matter

not miss of being made red-hot. Dr Black has also frequently seen the vapour of water heated by throwing it into the ash-pit of a furnace, so as to produce a very large and transparent flame in rising up through the vent. There is reason therefore to conclude, that ignition is one of the more general effects of heat, only that some bodies are incapable of it until they be reduced to a state of vapour.

on.

V. The last of the effects of heat here to be taken notice of is *inflammation*. It differs from ignition in this, that the bodies subject to the latter gradually grow cooler as soon as they are taken out of the fire, without undergoing any considerable change; while those subject to inflammation become continually hotter and hotter, communicating a vast quantity of heat to others, and undergoing a kind of decomposition themselves, insomuch, that by this means they have been thought to be reduced to their constituent principles or elements. Some substances indeed seem to be an excep-

133
Inflammati-
on decom-
pounds but
does not de-
stroy bodies

tion to this, as in the open air they burn totally away, without leaving any residuum or producing any foot. These are spirit of wine, sulphur, and especially inflammable air; which last, by a proper mixture with dephlogisticated air, may be so totally consumed, that scarce a fiftieth part of the two will remain. On a careful examination of these substances, however, we find that there is by no means a total consumption, or indeed, properly speaking, any consumption at all, at least if we measure the quantity of matter by the weight of the substance employed. Thus, if we are at pains to collect the vapour of burning spirit of wine, we will find, that an aqueous dew is collected, which sometimes equals the spirit of wine itself in weight. With regard to sulphur, the case is still more evident; for the vapour of this, when collected, not only equals but greatly exceeds the weight of the sulphur employed; and on burning dephlogisticated and inflammable air together, as much water is found to be produced as nearly equals the weight of both airs. In like manner, when we collect the ashes, water, foot, and oil, procured by burning any of the common inflammable substances, we will find, that they in general exceed the weight of the matter employed. The great waste of bodies by fire, therefore, is owing to the dissipation of the volatile principles they contain, which are carried off and rendered invisible by being mixed with the atmosphere.

136
Of the ex-
istence of
phlogiston.

The process of inflammation has long been explained from the presence of a substance called *Phlogiston* in those bodies which are subject to it, and which is supposed to be the same in all bodies belonging to this class; the differences between them arising from the principles with which it is combined. This doctrine, which was first introduced by Stahl, has given occasion to such various and discordant theories, that the existence of phlogiston has been lately denied altogether by M. Lavoisier, who brought in a new method of solving the phenomena of fire, heat, and ignition, without any assistance from this principle.

138
Arguments
against it
drawn from
the increa-
sed weight
of metals
by calcina-
tion.

The foundation of M. Lavoisier's doctrine is the increase of weight in metals by calcination. This increase he finds to be precisely, or very nearly so, proportionable to the decrease of weight in the air in which they are calcined. His theory, therefore, is, that in the act of calcination, the pure part of the air,

which he calls the *acidifying* or *oxygenous* principle, unites with the metal, and converts it into a calx. In like manner, in substances truly inflammable, the heat and flame are supposed to proceed from the union of the pure air, or the oxygenous principle, with the substance, and converting it into those principles which are found to remain after inflammation. Thus the increased weight of the substance is easily accounted for; while the inflammation, in his opinion, is nothing more than a combination of the inflammable body itself with pure air, which has an attraction for it: and in confirmation of this it is urged, that when combustion is performed in empyreal or dephlogisticated air, the whole of the latter is absorbed; but in common atmospherical air only one fourth, being the quantity of pure air contained in it.

Other arguments in favour of this opinion are, that the calces of the perfect metals may be reduced without addition by the mere emission of the oxygenous principle, (dephlogisticated air); by an union with which they assume the form of a calx. Thus he evades a very strong argument used by the opposite party; who adduced, as a proof of the existence of phlogiston, the use of charcoal in the reduction of metals to their proper form. A dispute indeed took place betwixt M. Lavoisier and Dr Priestley concerning the reduction of the whole of a mercurial calx formed by an union with the nitrous acid without addition; the Doctor maintaining, that the whole could not be reduced by mere heat, but that a very perceptible quantity was always lost: but on a thorough examination of the subject, the truth seemed rather to lie on M. Lavoisier's side. See AEROLOGY.

Another theory, somewhat similar to that of Lavoisier's, has been published by Dr Lubbock, in an Inaugural Dissertation in 1784. In this he supposes two kinds of matter to exist in the universe; one he calls the *principium proprium*, the other the *principium forbile*; and it is this latter, which, according to our author, is the principle of mutability, or which, by being united in various proportions with the other, forms bodies of all the different kinds we see in nature. It is this principle, therefore, which he supposes to be absorbed in the calcination of metals, and not empyreal air, as M. Lavoisier supposes; and he contends, that this same principle extends throughout the whole system of nature, even to the utmost celestial bounds.

It would exceed the limits of this treatise to give an account of the various theories which have been invented, and the arguments used for and against them; nor indeed is there any occasion for doing so, as late experiments have reduced the dispute into a much narrower compass than before, and furnished the most decisive arguments in favour of the existence, of phlogiston.

The greatest objection to the belief of this principle was, that it could neither be seen nor felt by our senses directly, nor discover itself indirectly by the weight it communicated to the bodies with which it was united; on the contrary, the latter always became lighter in proportion to the quantity they contained; so that it was imagined, instead of being possessed of any specific gravity of its own, to be a principle of positive levity, such as that of heat or light may be reasonably supposed. This objection, however, is now entirely removed; and phlogiston in the abstract is found

found to be no subtle principle capable of eluding our researches, but one very common, and easily met with, being no other than common charcoal. In the last edition of this work, under the article PHLOGISTON, it was shown, that inflammable air, deprived of its elasticity, and combined with metallic substances, is really their phlogiston; and that in the inflammable bodies commonly used, what we call their phlogiston, is really their oil; and that which exists in charcoal, and cannot be driven off by distillation, is part of the empyreumatic or burnt oil of the subject which adheres so obstinately. A similar doctrine soon after appeared in the Philosophical Transactions for 1782, and the identity of phlogiston and inflammable air was clearly proved by Mr Kirwan. Still, however, it was insisted by the French philosophers and others, that no *facts* had been adduced against M. Lavoisier, nor any decisive proofs appeared of the existence of phlogiston as a substance *per se*. Facts of this kind, however, have now been discovered by Dr Priestley, and are related under the articles AEROLOGY, CHARCOAL, PHLOGISTON, &c. It is sufficient at present to mention, that he has been able to convert the purest spirit of wine, and one of the hardest metals, viz. copper, as well as several others, into a substance entirely resembling charcoal; that by means of the heat of a burning glass in vacuo, he has dissipated this metallic charcoal, as well as the common kind, *entirely* into inflammable air, with the assistance only of a little water, which seems necessary to make it assume the aerial form, and perhaps is the true solvent of it; and by a combination with the element of heat, with the aid of the charcoal, is enabled to resist condensation in the common way*. This inflammable air, when absorbed by metallic calces, again reduces them to their metallic form: so that here is one fact by which the phlogiston not only appears to our senses, but we are able to ascertain its quantity with the utmost precision. Nor can it here be any objection, that the reduced metal is lighter than the calx; for this only proves that the metallic earth, while a calx, is united to a heavy ingredient (the basis of dephlogisticated air), and in the latter to a light one, viz. charcoal, the basis of inflammable air.

Another case in which the existence of phlogiston is made equally evident to our senses, and where no such objection can occur, is related under the article AEROLOGY, n° 112. It is there shown, that "by the loss of one grain of charcoal of copper (formed by the union of spirit of wine with the metal), and which like common charcoal was consumed without having any residuum, he reduced four ounce-measures of dephlogisticated air till only one-ninth remained unabsorbed by water; and, again, with the loss of one grain and a half of charcoal, six and an half measures of dephlogisticated air were reduced till five and an half measures were pure fixed air."—Here, then, is an absolute and undeniable evidence, that fixed air is composed of dephlogisticated air, and charcoal or phlogiston, and elementary fire. There were no other ingredients present, and the charcoal must either have been annihilated or disposed of in the manner just mentioned: but the superior weight of the fixed air evidently shows that some ingredient had been added to the dephlogisticated air; and which increase was more than we can

suppose to arise from the condensation of the dephlogisticated air during the operation, for this sometimes amounted to no more than one-thirtieth part.

The strongest objection which can be made against the doctrine of phlogiston may be drawn from the total consumption of pure air in certain cases of combustion, for instance, in that of phosphorus, inflammable air, and iron. It must be observed, however, that in no case whatever is the air totally consumed; and in that of inflammable air water is produced by the union of the basis of the latter, that is charcoal, with the basis of dephlogisticated air, the oxygenous principle of M. Lavoisier, and which appears to be one of the component parts of WATER. In the case of phosphorus, the latter is converted into an acid; and in all probability a quantity of water is also produced, by which part of it is converted into crystalline flowers. The case of the iron, therefore, alone remains to be considered. Dr Priestley's experiments on this subject are related at length under the article AEROLOGY, n° 67 *et seq.* In them the iron burnt briskly in dephlogisticated air, which, according to the common theory, should have indicated the expulsion of a great quantity of phlogiston; yet the whole residuum, of which the fixed air, produced by the supposed union of the phlogiston or principle of inflammability, was only a part, scarce amounted sometimes to one-fourteenth of the air originally employed.

This argument, however, instead of contradicting the existence of phlogiston, only shows, that in some cases the dissipation of a very small quantity of phlogiston is necessary to inflammation; or that the aerial principle may combine with the iron in its metallic state. In this case only a very little quantity of the phlogiston of the iron was dissipated; for it was not reduced to a calx, but to that kind of scoriae which flies off in scales by beating the metal when red-hot with an hammer. A decisive proof of this was had by uniting iron thus combined with the basis of dephlogisticated air with inflammable air. By this the metal was indeed reduced to perfect iron again; but water was produced at the same time from the union of the basis of the two airs, that of the inflammable air being capable of furnishing a superfluous quantity, which united with the other into the form of a fluid.

The existence of phlogiston being thus proved, and its nature ascertained, we may now proceed to determine the question, Whether the great quantity of heat produced by the combustion of inflammable bodies proceeds from the bodies themselves, or from the air which must be admitted to them in order to make them burn? That the heat in this case proceeds from the atmosphere is evident; because in all cases of combustion there is a certain diminution undoubtedly takes place by means of the conversion of the dephlogisticated part of the atmosphere into fixed air. It is proved, under the article *ELASTIC Vapours*, that elementary fire is the universal cause of elasticity in fluids. By uniting a certain quantity of it with any substance, the latter at length assumes an aerial or vaporous form; and it is this vapour alone which is inflammable*. Different vapours no doubt contain different quantities of these ingredients; but in all cases the basis of the dephlogisticated part of the atmosphere

must unite with the phlogiston of the inflammable body, or with something else, so that a decomposition may ensue: and it is this decomposition which produces the heat and light; for then the fire contained in the atmosphere having no longer any thing to absorb it, must appear in its proper form. But in those cases where there is a great quantity of phlogiston, and consequently much fixed air produced, the latter absorbs so much heat in a latent state, that the quantity communicated to surrounding bodies must be greatly diminished; and if by an excess of this ingredient, not only fixed air, but the phlogisticated kind and gross smoke be also produced, this diminishes the heat still farther by the great absorption, and will even destroy it altogether. The remedy for this is either to diminish the quantity of phlogiston, or to augment the quantity of air; which, by furnishing a greater quantity of dephlogisticated basis, affords an opportunity for the evolution of a greater quantity of heat. On the other hand, when the quantity of air is too great, the phlogistic matter cannot combine with the basis of the pure air in sufficient quantity to effect a decomposition; and therefore the heat is absorbed in a latent state, and the fire goes out.

From this theory, which is further illustrated under the articles FIRE, FLAME, HEAT, PHLOGISTON, &c. we may not only have a rational idea of the manner in which inflammation is generally accomplished, but see why a fire may be put out both by too great a quantity of fuel, and by too great a quantity of air. We may also see why the solar beams and electric fluid, which contain no phlogistic matter, excite a much more powerful heat than any we can raise in our hottest furnaces. The difference between ignition and inflammation will now likewise appear; such bodies as are capable only of ignition containing little or no phlogiston, but inflammable bodies a great deal.

The following table shows the most remarkable degrees of heat from the congelation of mercury to that of Mr Wedgewood's hottest furnace.

SECT. II. Of the Doctrine of Elective Attraction, and of the different Objects of Chemistry.

BEFORE we proceed to give a general theory of the changes which happen upon the mixtures of different bodies together, or exposing them singly to heat, we must observe, that all depend on certain qualities in bodies, by which some of them are apt to join together, and to remain united while they have an opportunity. The cause of these qualities is totally unknown; and therefore philosophers, after the example of Sir Isaac Newton, have expressed the apparent effect of this unknown cause by the word *attraction*. From them the word has been adopted by the chemists, and is now generally used in speaking of the phenomena which are observed in the mixture of different substances; but to distinguish it from other kinds, it is usually called *Elective*.

This attraction is not equally strong between all substances; in consequence of which, if any body is compounded of two others, and another is presented to it which has a greater attraction for one of the component parts than they have for one another, the substance will be *decompounded*. A new compound is then formed by the union of that third substance with one of the component parts or *elements* (if we please to call them so) of the first. If the attraction between the body superadded and either of the component parts of the other is not so strong as that between themselves, no decomposition will ensue; or if the third substance is attracted by both the others, a new composition will take place by the union of all the three.

The objects of chemistry, as we have already observed, are so various, that an enumeration of them all is impossible. To ease the mind, therefore, when speaking of them, and render more useful any thing that is said or wrote on chemistry, it is necessary to divide them into different classes, comprehending in each class those bodies which have the greatest resemblance to one another, and to which one common rule applies pretty generally.—The division formerly used, was that of vegetables, animals, and minerals; but this has been thought improper, as there are many substances in each of those kingdoms which differ very widely from one another, and which are by no means subject to the same laws. The most approved method,

163
Objects of
chemistry
how clas-
sed.

Salts. method, at present, of arranging the objects of chemistry, is into salts, earths, metals, inflammable substances, waters, animal and vegetable substances.

SECT III. Salts.

164
Salts.

SALTS are either *fusible*, that is, capable of abiding the fire, and melting in a strong heat, without being dissipated; or *volatile*, that is, being dispersed in vapour with a small heat. Their other properties are, that they are soluble in water; not inflammable, unless by certain additions; and give a sensation of taste when applied to the tongue.

The most general characteristic of salts is, that they are all soluble in water, though some of them with much more difficulty than others. Most of them have likewise the property of forming themselves, in certain circumstances, into solid transparent masses of regular figures, different according to the different salt made use of, and which are termed *crystals* of that salt. In this state they always contain a quantity of water; and therefore the utmost degree of purity in which a salt can be procured, is when it has been well crystallized, and the crystals are freed of their superfluous moisture by a gentle heat. They generally appear then in the form of a white powder.

165
Phenomena attending their solution.

In the solution of salts in water, the first thing observable is, that the water parts with the air contained in it; which immediately rises to the top in the form of bubbles. This, however, is most remarkable when the salt is in the dry form we have just now mentioned, because there is always a quantity of air entangled among the interstices of the powder, which rises along with the rest; and this discharge of air is sometimes so great, as to be mistaken for an effervescence. From this, however, it is essentially different. See EFFERVESCENCE.

Another thing observable in the solution of salts is, that a considerable change happens in the temperature of the water in which they are dissolved; the mixture becoming either a good deal warmer or colder than either the salt or the water were before. In general, however, there is an increase of cold, and scarce any salt produces heat, except when it has been made very dry, and deprived of that moisture which it naturally requires; and thus the heating of salts by being mixed with water may be explained on the same principle with the heat produced by quicklime. See QUICKLIME.

After salt has been dissolved in a certain quantity by water, no more of that salt will be taken up unless the water is heated; and as long as the heat continues to increase, the salt will be dissolved. When the water boils, at which time it has attained its greatest heat, and will take up no more salt, it is then said to be *saturated* with that salt. This, however, does not prevent it from taking up a certain quantity of another salt, and after that perhaps of a third, or fourth, without letting go any of the first which it had dissolved. How far this property of water extends, has not yet been ascertained by experiments.

To the above rule there is only one exception known as yet; namely, common sea-salt: for water dissolves it in the very same quantity when cold as when boiling hot. It has been said by some, that all deliquescent salts, or those which grow moist on being

exposed to the air, had the same property: but this is found to be a mistake.

This property of solubility, which all the salts possess in common, renders them easily miscible together; and the property by which most of them shoot into crystals, renders those easily separable again which have no particular attraction for one another. This is likewise rendered still more easy by their requiring different proportions of water, and different degrees of heat, to suspend them; for by this they crystallize at different times, and we have not the trouble of picking the crystals of one out among those of the other.

The manner in which the solution of salts in water is effected, is equally unaccountable with most of the other operations of nature. Sir Isaac Newton supposed that the particles of water got between those of the salt, and arranged them all at an equal distance from one another: and from this he also accounts for the regular figures they assume on passing into a crystalline form; because, having been once arranged in an orderly manner, they could not come together in disorder, unless something was to disturb the water in which they were suspended; and if any such disturbance is given, we find the crystals are by no means so regular as otherwise they would have proved. Others have thought that these figures depend on a certain *polarity* in the very small particles into which the salt is resolved when in a state of solution. These things, however, are merely conjectural; neither is it a matter of any consequence to a chemist whether they are right or wrong.

Though solution is that operation which salts undergo the most easily, and which should seem to affect them the least of any, a repetition of it proves nevertheless very injurious to them, especially if it is followed by quick evaporation; and the salt, instead of being crystallized, is dried with a pretty strong heat. Newman relates, that a pound of sea-salt was reduced, by 13 solutions and exsiccations, to half an ounce; and even that was mostly earth. Where solution is required, therefore, it ought always to be done in close vessels, in which also the subsequent evaporation should be performed, (see EVAPORATION); and in all cases where crystallization is practicable, it ought to be preferred to violent exsiccation.

The two great divisions of salts are into acids and alkalies. The former of these are known by their peculiar taste, which is called *acid* or *sour*. They are not found in a solid form; neither are any of them, except the acids of vitriol, of tartar, of phosphorus, and of borax, capable of being reduced to solidity. The others, when highly concentrated, that is, brought to the utmost degree of strength of which they are capable, always become an invisible vapour, permanently elastic, until it comes in contact with water, or some other substance with which they are capable of uniting. For such acids the name of *salts* seems less proper, as we can scarcely say that a *vapour*, which is already much more fluid than water, can be *dissolved* in that element.

The acids are divided into the mineral, the vegetable, and the animal; expressing their different origin, or where they are most commonly to be found. The mineral acids are commonly reckoned three; the

Acids.

Salts.

vitriolic, the nitrous, and the marine. To this the acid of borax ought to be added; but its weakness makes it much less taken notice of as an acid than the others. A Swedish chemist, however, Mr Scheele, hath lately added several others, which are afterwards taken notice of.

The vegetable kingdom affords only two distinct species of acids, at least without the assistance of some chemical operation. The one appears fluid, and when concentrated to the utmost degree becomes an invisible vapour. This is produced from fermented liquors, under the name of *vinegar*. An acid similar to this, and which is thought not to be essentially different from it, is extracted from most vegetables by distillation with a strong fire. The other is likewise a consequence of fermentation; and crusts on the bottom and sides of casks in which wine is put to depurate itself. In its crude state it is called *tartar*; and when afterwards purified, is called the *cream*, or crystals, of tartar. As for the various acids produced in the different chemical processes to be afterwards related, we forbear to mention them at present, it being justly suspected that some of them are artificial.

The animal acids, which have hitherto been discovered, are only two; the acid of ants, and that of urine, which is also the acid of phosphorus. The first of these is volatile; and consequently must be supposed a vapour when in its strongest state: the other is exceedingly fixed; and will rather melt into glass than rise in vapours. Besides these, it is said an acid is contained in blood, in wasps, bees, &c.: but no experiments have as yet been made on these to determine this matter with any degree of precision.

170
Alkalies.

The alkalies are of two kinds; fixed and volatile. The fixed kind are subdivided into two; the vegetable, and mineral or fossil alkali. The vegetable is so called, because it is procured from the ashes of burnt vegetables; the fossil, because it is found native in some places of the earth, and is the basis of sea-salt, which in some places is dug out of mines in vast quantity. They are called *fixed*, because they endure a very intense degree of heat without being dissipated in vapour, so as even to form a part of the composition of glass. The volatile alkali is generally obtained by distillation from animal substances. In its pure state this alkali is perfectly invisible; but affects the sense of smelling to such a degree, as not to be approached with safety.

171
Different
action of
alkalies and
acids.

The acids and alkalies are generally thought to be entirely opposite in their natures to one another. Some, however, imagine them to be extremely similar, and to be as it were parts of one substance violently taken from each other. Certain it is, that when separated, they appear as opposite to one another as heat and cold. Their opposite action indeed very much resembles that of heat and cold, even when applied to the tongue; for the alkali has a hot, bitter, burning taste, while the acid, if not considerably concentrated, always gives a sensation of coldness. In their action too upon animal substances, the alkali dissolves, and reduces the part to a mucilage; while the acid, if not very much concentrated, tends to preserve it uncorrupted.

172
Neutral
salts.

If an alkaline salt, and moderately strong acid in a liquid state, be mixed together, they will immediately

unite; and, provided the alkali has not been deprived of its fixed air, their union will be attended with a very considerable effervescence: (see AEROLOGY.) If the alkali has been deprived of air, no effervescence will ensue, but they will quietly mix together; but if a due proportion of each has been added, the liquor will neither have the properties of an acid nor an alkali, but will be what is called *neutral*. The bringing the liquor into this state, is called *saturating* the acid or alkali, or combining them to the point of saturation.

If the liquor after such a saturation be gently evaporated, a saline mass will be left, which is neither an acid nor an alkali, but a new compound formed by the union of the two, and which is called a *perfect neutral salt*. The epithet *perfect* is given it, to make a distinction between the salts formed by the union of an acid and an alkali, and those formed by the union of acids with earthy or metallic substances; for these will likewise unite with acids, and some of the compounds will crystallize into regular figures; but, because of their weaker union with these substances, the salts resulting from combinations of this kind are called *imperfect*.

All acids, the volatile sulphureous one excepted, change the blue infusions of vegetables, such as violets, to a red; and alkalies, as well as some of the imperfect neutrals, change them to green. This is the nicest test of an acid or alkali abounding in any substance, and seems the most proper method of determining whether a solution intended to be neutral really is so or not.

173
Vegetable
colours
changed by
acids and
alkalies.

Though between every acid and alkali there is a very strong attraction, yet this is far from being the same in all; neither is it the same between the same acid and alkali in different circumstances of the acid. When the acids are in a liquid state, and as free as possible of inflammable matter, between which and the nitrous and vitriolic acids there is a very strong attraction, the vitriolic will expel any of the rest from an alkaline basis, and take its place. Thus, if you combine the acid of sea-salt, or marine acid, to the point of saturation, with the fossil alkali, a neutral salt will be formed, which has every property of common salt: but, if you pour on a certain proportion of the vitriolic acid, the acid of sea-salt will immediately be expelled; and the liquor, upon being evaporated, will contain not the neutral salt formed by an union of the marine acid with the alkali, but another consisting of the vitriolic acid joined with that alkali, and which has quite different properties from the former.

174
Differences
in the de-
grees of at-
traction be-
tween acids
and alkalies.

When the acids and alkalies are applied to one another in a liquid state, the vitriolic acid always shows itself to be the most powerful; but when applied in a solid form, and urged with a violent heat, the case is very much altered. Thus, the acid of borax, commonly called *sal sedativus*, is so weak as to be disengaged from its basis by every acid applied in a liquid form, that of tartar alone excepted; but if even the vitriolic acid combined with an alkali be mixed with this weak acid, then exsiccated, and at last urged with a vehement fire, the vitriolic acid will be disengaged from its basis, and rise in vapours, leaving the weaker acid in possession of the alkali. The same thing happens on adding the phosphoric or urinous acid,

Salts.

acid, or the acid of arsenic, &c. to combinations of the vitriolic or other acids with alkaline salts.—When the acids are in a liquid state, therefore the most powerful is the vitriolic; next the nitrous; then the marine; then vinegar; acid of ants; and lastly the sal sedativus and tartar, which seem to be nearly equal in this respect.—If they are applied in a solid form, the most powerful are the sal sedativus and phosphorine acid; then the vitriolic, nitrous, marine, and vegetable acids.

When they are reduced to vapour, the case is exceedingly different; for then the marine acid appears to be the most powerful, and the vitriolic the least so of any. It is impossible, however, to preserve the vitriolic acid in the form of vapour, without combining it with a certain quantity of inflammable matter, which must necessarily destroy its strength. Dr Priestley found, that the marine acid, when reduced to vapour, was capable of disuniting the nitrous acid from a fixed alkali.

Though the vitriolic acid sometimes assumes a solid form, it is by no means easy to reduce it to this state by mere concentration, without the assistance of nitrous acid. Baldasart, however, pretends that he discovered, in the neighbourhood of a volcano, a pure and icy oil of vitriol, from which nothing could be precipitated by alkaline salts; though there is certainly very great reason to doubt the accuracy of this observation. Of late the nitrous acid has also been found capable of assuming a solid form. This was first observed by M. Bernhard in distilling a very large quantity of the acid. At that time he perceived a white salt adhering to the inside of the receiver, which on examination proved to be the acid of nitre in a concrete form; being extremely corrosive, emitting red vapours copiously on being exposed to the air, and at length totally evaporating in it. Its specific gravity, however, was far inferior to that of the glacial oil of vitriol.

175
Acids unite
with phlogiston.

The acids have the property of uniting themselves to many other substances besides fixed alkalies, and forming neutral compounds with them. Of these the chief is the principle of inflammability or phlogiston. In the vitriolic, nitrous, and phosphorine acids, the attraction for this principle is very strong; so great, that the two former will even leave a fixed alkali to unite with it. In the marine acid it is less perceptible; in the liquid vegetable or animal acid still less; and in the acid of tartar, and sal sedativus, not at all.

176
With metals and earth.

Besides this, all acids will dissolve metallic and earthy substances: with these, however, they do not in general unite so firmly with alkaline salts; nor do they unite so strongly with metals as with earths.

177
Electric attractions

In general, therefore, we may expect, that after having dissolved a metal in any acid whatever, if we add an earthy substance to that solution, the acid will quit the metal, which it had before dissolved, to unite with the earth. In this case the solution will not be clear as before, but will remain muddy, and a quantity of powder will fall to the bottom. This powder is the metalline substance itself, but deprived of one of its component parts; and in this case it is said to *precipitate* in the form of a *calx*.

If to this new solution of the earthy substance in an acid liquor, a volatile alkaline salt, not deprived of its

fixed air, is added, the acid will quit the earth, and unite with the alkaline salt. The earth thus disengaged will again *precipitate*, and lie at the bottom in fine powder, while the volatile alkali and acid remain combined together, and the liquor again becomes clear.

The attraction between volatile alkalies and acids is considerably less than between fixed alkalies and the same acids. If, therefore, a fixed alkali be now added to the liquor, the volatile alkali will be separated, and the acid will unite with the fixed alkali. The volatile alkali indeed, being perfectly soluble in water, cannot precipitate, but will discover its separation by the pungent smell of the mixture; and upon evaporating the liquor, the volatile alkali will be dissipated, and a saline mass, consisting of the acid and fixed alkali, will remain.

Lastly, If the acid employed was the nitrous, which has a strong attraction for the principle of inflammability, if the saline mass be mixed with a proper quantity of inflammable matter, and exposed to a strong heat, the acid will leave the alkali with vast rapidity, combine with the inflammable matter, and be destroyed in flame in a moment, leaving the alkali quite pure.

Though the above-mentioned effects generally happen, yet we are not to expect that they will invariably prove the same whatever acid is made use of; or even that they will be the same in all possible variety of circumstances in which the same acid can be used.—The acid of tartar is one exception, where the general rule is in a manner reversed; for this acid will quit a fixed alkali for an earth, especially if calcined, and even for iron. If lead, mercury, or silver, are dissolved in the nitrous acid, and a small quantity of the marine acid is added, it will separate the stronger nitrous acid, and fall to the bottom with the metals in form of a white powder.—The vitriolic acid, by itself, has a greater attraction for earthy substances than for metals; and greater still for fixed alkaline salts than for either of these: but if quicksilver is dissolved in the nitrous acid, and this solution is poured into a combination of vitriolic acid with fixed alkali, the vitriolic acid will quit the alkali to unite with the quicksilver. Yet quicksilver by itself cannot easily be united with this acid. The reason of all these anomalies, however, is fully explained in the following section.

§ 1. Of the Operations of Solution and Precipitation.

THE chemical solution of solid bodies in acid or other menstrua, is a phenomenon which, though our familiarity with it has now taken off our surprise, must undoubtedly have occasioned the greatest admiration and astonishment in those who first observed it. It would far exceed the limits of this treatise to speak particularly of all the various circumstances attending the solution of different substances in every possible menstruum. The following are the most remarkable, collected from Mr Bergman's Dissertation on Metallic Precipitates.

1. On putting a small piece of metal into any acid, it is dissolved sometimes with violence, sometimes gently, according to the nature of the menstruum and of the metal to be dissolved.

2. The nitrous acid is the most powerful in its action.

Salts.

Solution
and Preci-
pitation.

181

Nitrous acid
the most
violent in
its opera-
tion.

tion upon metallic substances, when unassisted by heat. So great indeed is the violence with which this acid sometimes acts, that the metal, instead of being dissolved, separates instantaneously from it in the form of a calx or powder scarce soluble in any menstruum, at the same time that the heat, effervescence, and noxious vapours issuing from the mixture, render it absolutely necessary to moderate the action of the menstruum, either by dilution or cold, or both. In other cases, however, as when put to gold or platina, the nitrous acid has no effect until it be united with the marine, when the mixture acts upon those metals, which neither of the acids singly would touch.

182

Vitriolic
acid acts
more weak-
ly.

3. The action of the vitriolic acid, though in the highest degree of concentration, is more weak. It does not readily attack silver or mercury unless assisted by a boiling heat, nor will even that be sufficient to make it act upon gold or platina.

183

Marine acid general-
ly more
weak than
either, ex-
cept when
dephlogisti-
cated.

4. The action of marine acid, unless on some particular substances, is still more weak; but when dephlogistified, or deprived of part of the phlogiston essential to its constitution as an acid, it acts much more powerfully, and dissolves all the metals completely.

184

The rest of
the acids
much
weaker still.

5. The other acids, as those of fluor, borax, with such as are obtained from the animal and vegetable kingdoms, are much inferior in their powers as solvents, unless in very few instances.

185

Different
degrees of
solubility in
metals.

6. Metals vary very much in their degrees of solubility; some yielding to almost every menstruum, and others, as has been already observed, being scarce acted upon by the most powerful.

186

Solution
sometimes
promoted
by abstract-
ing a cer-
tain pro-
portion of
phlogiston.

6. Zinc and iron are of the former kind, and gold and silver of the latter, eluding the marine; and gold, unless in one particular case, viz. when assisted by heat in a close vessel, the action of the nitrous acid also. These metals, however, which in their perfect state resist the action of the most powerful menstrua, may be dissolved much more readily when deprived of a certain quantity of their inflammable principle. But though the separation of this principle in some degree renders metals more soluble, the abstraction of too much of it, particularly in the case of iron and tin, renders these metals almost entirely insoluble. Manganese is the most remarkable instance of this power of the phlogistic principle, in depriving metals of their solubility by its absence, or restoring it to them by its presence; for this substance, when reduced to blackness, cannot be dissolved by any acid without the addition of some inflammable matter; but when by the addition of phlogiston it has become white, may be dissolved in any acid.

188

Solution of
metals at-
tended with
an effervescence.

7. The dissolution of metals by acids, even to their very last particle, is attended by a visible effervescence: this is more perceptible according to the quickness of the solution; but more obscure, and scarcely to be seen at all, when the solution proceeds slowly.

189

Various
kinds of e-
lastic fluids
extricated.

8. The elastic fluids extricated by these solutions are various, according to the nature of the acid and of the metal employed. With the nitrous, the fluid produced is commonly that called *nitrous air*; with vitriolic and marine acids the produce is sometimes inflammable air, sometimes otherwise, according to the nature of the metal acted upon.

9. Heat in a greater or smaller degree is always produced during the dissolution of metals; and the de-

No 70.

6

gree of it is in proportion to the quantity of the matter and the quickness of the solution; and hence, in small quantities of metal, and when the solution proceeds very slowly, the temperature of the mass is scarcely altered.

10. The calces of metals either yield no air at all, or only the aerial acid, unless when urged by a violent heat almost to ignition; when, by means of vitriolic or nitrous acid, they yield a quantity of pure air, after other elastic fluids, such as vitriolic, nitrous, or phlogistified air. None of the dephlogistified air is usually produced by the marine acid in conjunction with metallic calces.

11. The solutions of some metals are coloured, others are not. The colour of the former is only that which is proper to the calx, but rendered more vivid by the moisture. Thus solutions of gold and platina are yellow; those of copper, blue or green; solutions of nickel of a bright green; but those of cobalt are red, although the calx is black. We may observe that even this red colour may be heightened to blackness. Iron moderately calcined is green; but this rarely continues upon further dephlogistification. The white calces of silver, lead, tin, bismuth, arsenic, antimony, and manganese, are dissolved without colour; but solutions of lead, tin, and antimony, are somewhat yellow, unless sufficiently diluted. Mercury, however, forms a singular exception to this rule; for the orange-coloured calx of this metal forms a colourless solution. The metals yielding coloured solutions are gold, platina, copper, iron, tin, nickel, and cobalt; the rest, if properly depurated, give no tinge. A solution of silver is sometimes of a blue or green colour at first, although there be no copper present; the vitriolic acid becomes blue with copper; the nitrous may be made either blue or green at pleasure; the marine varies according to the quantity of water with which it is diluted. Manganese, when too much dephlogistified, renders both the vitriolic and marine acids purple.

With regard to the cause of chemical solutions, our author observes, that though attraction must be looked upon as the fundamental cause, yet we may also lay it down as a maxim, that no metal can be taken up by an acid, and at the same time preserve the whole quantity of phlogiston which was necessary to it in its metallic state. A certain proportion of the principle of inflammability therefore may be considered as an obstacle which must be removed before a solution can take place. Thus, of all the acids, the nitrous attracts phlogiston the most powerfully, and separates it even from the vitriolic. A proof of this may be had by de-boiling sulphur slowly in concentrated nitrous acid. At length all its phlogiston may be separated, and the vitriolic acid will remain, deprived of its principle of inflammability. The extraordinary solvent powers of this acid, therefore, is conformed to the peculiarity of its nature in this respect. For this menstruum dissolves metals for solution with the greatest ease, most commonly without any assistance from external heat; which in some instances would be hurtful, by separating too much of phlogiston, as appears in the case of iron, tin, and antimony; all of which may be so far dephlogistified by the nitrous acid, as to be rendered extremely difficult of solution: for this reason it is very often necessary, as has already been observed, to temper the activity

activity of this menstruum by water. The vitriolic acid requires a boiling heat before it can act upon silver or mercury. The reason of this is, that by means of the heat, the watery part of the menstruum is diminished, its power is thereby increased, and the connection of the metallic earths with the inflammable principle diminished. Marine acid, which contains phlogiston as one of its constituent principles, must necessarily have little or no effect on those metals which retain their principle of inflammability very obstinately. But its watery part being diminished by boiling, it assumes an aerial form, and powerfully attracts a larger quantity of phlogiston than before; so that in a vaporous state it will dissolve metals, particularly silver and mercury, which in its liquid form it would scarce be brought to touch. When dephlogisticated as much as possible, it attracts phlogiston with prodigious avidity, dissolving all metals by its attraction for their phlogiston, and, uniting the inflammable principle to itself, resumes the ordinary form of marine acid. When dephlogisticated by means of nitrous acid in aqua regis, it dissolves gold and platinum. On the same principles may we account for its inferiority in power to the other acids.

It has already been observed that the metals differ much in their degrees of solubility, which is owing to the various degrees of force with which they retain their phlogiston. Those called perfect metals effectually resist calcination in the dry way. In this operation, the fire on the one hand, the great cause of the volatility of bodies, strenuously endeavours to expel the phlogiston; on the other hand, the basis of the dephlogisticated part of the atmosphere (the acidifying principle of M. Lavoisier, and the *principium sordibile* of Dr Lubbock) attracts the calx strongly. Experience, however, shows, that these two forces united, cannot decompose gold, silver, or platinum to any considerable degree. All the other metals yield to these forces when united, but not singly. Iron and zinc retain their inflammable principle so slightly, that any acid immediately acts upon them; but if the other metals be properly prepared for solution by being calcined to a certain degree, the acid will immediately take them up. Any further privation, however, would be injurious, and precipitate what was before dissolved. Thus the nitrous acid, when added to a solution of tin or antimony in marine acid, by its extraordinary attraction for phlogiston carries off such a quantity of it, that the calces of the metals are immediately precipitated.

The various elastic fluids which resemble air, and which are produced in plenty during the dissolution of metals, may be reduced to the following, viz. those extricated by the vitriolic, nitrous, and marine acids, fluor acid, vinegar, alkaline salts, and hepar sulphuris.

Pure vitriolic acid exposed to a violent heat, is indeed resolved into vapours, but of such a nature, that when the heat is gone, they condense again into an acid liquor of the same nature as before. But if any substance be added which contains phlogiston in a separable state, an elastic fluid is produced by means of fire, which is scarcely condensable by the most extreme cold, unless it comes in contact with water. This is called the volatile sulphureous acid, or vitriolic acid air, which may be totally absorbed by water. In this case the bond of union betwixt it and the phlogiston

is so weak, that the latter soon flies off totally, and common vitriolic acid is regenerated.

The nitrous acid undergoes a similar change in a more obvious manner. Let a piece of silver, for instance, be put into a dilute nitrous acid, and the surface of the metal will instantly be covered with innumerable bubbles, which arising to the top of the liquor, there burst; and if collected, are found to be nitrous air. The nitrous acid saturates itself with phlogiston more completely than the vitriolic; therefore the elastic fluid produced, or nitrous air, does not unite with water, and scarce retains any vestige of an acid nature. The vitriolic acid, however, differs from the nitrous in this respect, that the phlogiston is absorbed by the latter even beyond the point necessary to obliterate its acid nature. In proof of this, our author adduces the decomposition of hepatic by means of nitrous air.

The marine acid exhibits different phenomena. It naturally contains phlogiston, and therefore can by its means be resolved into a kind of air somewhat similar to that produced by the vitriolic acid when artificially united to the same principle, and which has the same property, viz. that of remaining permanently elastic as long as it is kept from the contact of water. But as the acid we speak of naturally contains phlogiston, there is no necessity of adding more to produce this effect. In the mean time, the marine as well as nitrous air, when in its expanded state, attracts phlogiston, and that with wonderful avidity.

When the marine acid is dephlogisticated, it yields another elastic fluid of a reddish brown colour, having an odour like that of warm aqua regia. This does not unite with water, or only in very small quantity; and by the addition of a proper proportion of phlogiston may be reduced again to common marine acid. It is said that the marine acid may be dephlogisticated by lead as well as by manganese, the nitrous acid, and arsenic.

The fluor acid abounds with phlogiston, and therefore may, without any adventitious matter, be reduced to an elastic fluid. This air is easily distinguished from all others by its corrosion of glass whilst hot.

Vinegar also contains phlogiston; and for that reason, when well dephlegmated, may be reduced without addition into a permanently elastic fluid, called acetous air.

All these fluids seem to be nothing else, according to Mr Bergman, than the acids themselves expanded by phlogiston. "Perhaps (says he) the matter of heat also enters their composition." The experiments lately made on these subjects, however, have put it beyond all doubt, that the expansive principle is not phlogiston but heat; nevertheless, it seems highly probable, that these elastic fluids do really consist of the acid united to phlogiston, and expanded by heat. This is also the case with the caustic volatile alkali, now called alkaline air.

In the hepatic air, it has been shown by Mr Bergman, that sulphur exists which contains phlogiston; and there is little reason to doubt that the expansive power here is the same as in other cases. See HEPATIC AIR.

The heat generated during the solution of metals is by Mr Bergman supposed to be owing to the matter

of heat which had been fixed in the metals; but it may with much more reason be supposed to proceed from the acid. Dr Black has demonstrated, that heat is universally the principle of fluidity; and all fluids, whether acid or not, are found to contain a great quantity of it. It is not probable that solids, even the most inflammable, contain an equal quantity; for it is always observed, that bodies in becoming fluid absorb heat, and throw it out again on becoming solid. Acids in all probability contain a much greater quantity than what is necessary to their fluidity; for we see that the nitrous acid, when poured upon snow, parts with as much heat as is necessary to dissolve the snow, at the same time that it still retains its fluidity. The case is not so with common salt, which is a solid: for though, in a mixture of salt and snow, the latter absorbs as much heat from the salt as is necessary for its own liquefaction; yet the salt could not be held in solution by a liquid of this temperature, were it not that an additional quantity is perpetually absorbed from the adjacent bodies, particularly the atmosphere. But were it possible to prevent this adventitious increase of heat, there is not the least reason to believe that the salt would be dissolved; for the strongest brine, when reduced to the temperature of 0 of Fahrenheit, is decomposed, the salt falling to the bottom in powder, and the water being converted into ice. Add to this also, that the cold produced by spirit of nitre and snow is much more intense than that produced by common salt and snow; which undoubtedly shows, that a solid does not readily part with as much heat as a fluid, and consequently cannot be supposed to contain as much. The solution of metals in acids also demonstrates, that the solid substance has not parted with heat, but absorbed it; for as soon as the solution becomes solid again, *i. e.* when it crystallizes, the temperature becomes higher than before.

212
Solid bo-
dies do not
part with

heat as
fluids.

213
Why little
or no ela-
stic fluid is
obtained
from me-
tallic cal-
ces.

The calces of metals have not that quantity of phlogiston that is necessary for their metallic state, but yet are not entirely destitute of it; therefore, in their solution, scarce any elastic fluid is generated, unless the fire be continued after exsiccation. Such as contain aerial acid, discharge it immediately in the same form as they had received it. It is remarkable, that Dr Priestley mentions a calx of lead, which, with the acid of phosphorus, produced an inflammable air. By means of the nitrous acid and evaporation to dryness, a pure air is produced. Sometimes a small portion of vitriolic acid air is obtained by means of a proper degree of fire from vitriolic acid, but a far greater quantity of pure air.

214
Metallic
solutions
contain a
calx of the
metal with
various de-
grees of
phlogiston.

The solutions made by the menstrea above mentioned, contain a metallic calx intimately united with the acid, the quantity of phlogiston left being various according to the difference of the menstrea and of the temperature; but the performance of the operation either with or without intense heat, frequently occasions a remarkable difference. That metals are less calcined by the marine than by the nitrous acid, appears from pouring concentrated nitrous acid on tin or antimony; but the difference, if it actually does take place, is less visible in other metals.

Some modern chemists have denied this calcination of metals by solution. They have insisted, that the perfect metals ought to be excepted, as they do not

yield to the most intense fire. On this subject, however, it may be observed, 1. That during their solution nitrous air is always generated, and that of a very perfect kind, which cannot happen without phlogiston; but in this case there is nothing present which can yield phlogiston except the metals. Therefore, 2. The metals, when precipitated from their menstrea by fixed alkalis, both with respect to their external appearance and internal properties, appear to be calcined. Thus the precipitate of gold refuses to unite with mercury, and may be dissolved by marine acid and other simple menstrea, and that without the production of any elastic fluid. 3. Glass may be stained by these calces; but no metal in its perfect state can be taken up by glass.

The common objection is, that the calces of the perfect metals may be reduced by heat alone without the addition of charcoal. Many theories have been invented to solve this phenomenon. Some have supposed, that the matter of heat and light are the same with the phlogiston, and that thus the calces are reduced in the same manner as by charcoal or other substances usually termed *phlogistic*. But in this case we ought to find the calces of the imperfect metals also reduced by a long continuance of heat, as well as the more perfect; which, however, has never yet been known to take place. Some, among whose number is Dr Lewis, have imagined, that the porosity of the vessels, particularly those made of earthen ware, may be such as to admit the passage of phlogistic vapours through them; and he instances the revival of globules of lead in the middle of pieces of glass upwards of an inch in thickness, and that where there was not the least appearance of a crack. But from an experiment of Mr Kirwan's, to be afterwards related, it is much more probable that the reduction is effected by means of the phlogiston contained in one part of the calx attracted by another; by which means the latter is reduced to a perfect metal, while the former becomes somewhat more dephlogisticated. In consequence of this it appears, that the calx of the perfect metals is never totally reduced: for if the operation be performed in a glass retort, the bottom of it is always stained; which indicates the existence of a calx, in however little quantity.

The following fact, Mr Bergman says, has been proposed to him as an inextricable dilemma. "Silver cannot amalgamate with mercury except when in its metallic state, yet both salited and nitrated silver are taken up by mercury; it is therefore not calcined by the acids, but adheres to them in its metallic form." Bergman. This, however, may be easily solved in the following manner. It is well known that the calx of copper, dissolved in the vitriolic acid, is precipitated in its metallic form on the addition of iron, and that by means of a double elective attraction; for the iron, dissolving in the acid, would form an inflammable air by its phlogiston, were not the copper present which takes it up, and thereby becomes insoluble as long as it retains it; but mercury has a stronger attraction for acids than silver: if therefore salited or nitrated silver be triturated with mercury, the silver must be precipitated in a metallic state, and the mercury be calcined by being dissolved. This also takes place, provided there be moisture sufficient to suffer the elective attractions

tions to operate. The superabundant mercury greedily takes up the comminuted silver precipitate; and the *arbores Digna* are nothing more than such an amalgam crystallized. But although the acids cannot take up any metal while it retains its full proportion of phlogiston, various metallic salts are able to effect that solution. Thus nitrated or salited mercury, boiled in water together with the crude metal, can take up a certain portion of it without dephlogistication; and the latter of these salts, even in the *via sicca*, becomes a *mercurius dulcis*, which contains at the same time a crude and a calcined mercury.

218
Phlogiston
the cause
of colour
in metal-
lic solu-
tions.

Perfect solutions should in general be transparent; but some, as has been already mentioned, are distinguished by a peculiar colour. That phlogiston is the chief cause of colour appears from hence, that the black calx of manganese tinges vitriolic acid of a red colour; but on the addition of sugar the tinge is entirely destroyed. Nitrous acid is rendered blue by copper; but when the metal is added in considerable quantity, it becomes of a very deep green. The marine acid, which dephlogisticates the copper less, is yet made green; but by dephlegmation may be so condensed as to become brown. Mr Bergman has sometimes seen a solution of silver green, without the presence of the smallest particle of copper. This depends on the absorption of nitrous air: for let smoking nitrous acid be diluted, on the addition of a certain quantity of water it will be of a deep green; by a greater, blue; and upon a still greater, becomes limpid. By means of the water, the nitrous air is extended to a greater space; and this attenuation gradually increased varies the colours. Hence we see why nitrous acid is made green by a large quantity of copper.

219
Attraction
of phlo-
giston the
cause of
causticity.

Metals dephlogisticated by acid solvents powerfully attract phlogiston; nay, nitrated silver and mercury, and salited antimony, corrode animal substances, in order, as our author supposes, to extract it. "This metallic causticity (says he), which is only to be moderated by phlogiston, ought to be carefully distinguished from the acid causticity, which is repressed by alkalies, and the alkaline, which is mitigated by acids. Colours vary according to the quantity of phlogiston present; and some experiments show, that by a sufficient quantity all colour is entirely destroyed.

320
Phenome-
na attend-
ing the
precipita-
tion of me-
tals by al-
kaline salts.

All metals may be precipitated by alkaline salts; which, by their superior power of attraction, separate them from their menstrea; but their difference with regard to their nature and preparation alters the nature of the precipitate. With the caustic fixed alkali the calces fall almost entirely pure, but loaded with water. The weight is found to be increased by the water, and perhaps (says Mr Bergman) by the matter of heat; but yet less than by the aerial acid. With the aerated fixed alkali, by means of a double decomposition, the aerial acid unites to most calces. The volatile alkali, which naturally contains phlogiston, sometimes phlogisticates the precipitate. It throws down a black or white precipitate of mercury; nay, it makes the orange-coloured precipitate white. Gold receives its fulminating quantity from this precipitant, as is afterwards to be explained. The alkali, which is commonly called *phlogisticated*, generally precipitates metals with an increase of weight.

The acids frequently occasion precipitates, and that for various reasons. By means of elective attraction, mercury, silver, and lead, are taken from the nitrous acid by the addition of the marine or vitriolic. These acids form with the metals new compounds which are difficult of solution in water; they are therefore precipitated in greater or lesser quantity according to circumstances. The nitrous acid is capable of decomposing salited tin and antimony by dephlogisticating the calx of the metals too much; for when these are too much calcined, they cannot be dissolved in any menstruum, as has been already observed.

Metallic solutions are sometimes disturbed by the neutral salts formed by an union of alkalies with acids. Those which contain the vitriolic or marine acids decompose solutions of silver, mercury, or lead, in nitrous acid, and precipitate the metals. By forming a triple combination, the vegetable as well as the volatile alkali, though saturated with vitriolic, nitrous, or marine acid, precipitate platina from aqua-regia; but when the basis is mineral alkali, the salt has no power of this kind. Some metallic salts can decompose others, and precipitate their bases; which may happen whether the acid be different in the two salts or not. Solution of gold affords an example of each of these cases. This is precipitated by martial vitriol; the reason of which will appear from considering the nature of the precipitate: for this, when well washed and dried, not only shows many shining gold-coloured particles, but also unites with mercury by trituration, dissolves in aqua-regia, but not in marine acid alone, together with other circumstances which evince a complete resuscitation of the gold. Martial vitriol, in its ordinary state, contains phlogiston, but very loosely adhering; so that the calx of gold may easily take it from the solution to supply the loss it had sustained during the solution. That this is the true foundation of the process, appears also from the following circumstances, that the weight of the gold is exactly recovered, and that dephlogisticated vitriol will not precipitate this metal. The reason that the surrounding aqua-regia leaves this precipitate untouched is, that the menstruum is diluted and weakened by a large quantity of water; for upon boiling it gently, so as to expel part of the water, the menstruum recovers its solvent power, and takes up the precipitate again.

It is somewhat more difficult to explain the reason why the solution of gold in aqua-regia should be precipitated by a solution of tin in the same menstruum. Here Mr Bergman first supposed that the tin had attracted a superabundance of acid, and taken it from the gold; which being therefore destitute of its proper quantity, must fall to the bottom: but on employing a solution containing a superabundant aqua regia, the same precipitation took place. The cause is therefore not in the menstruum. On examining the precipitate itself, we find nothing like the metallic splendor of gold, but that it entirely resembles a calx. It is easily found by its weight, indeed, that it cannot consist entirely of gold; and in fact chemical examination shows that it consists partly of tin. It cannot be dissolved by the marine acid alone, but is easily taken up by the addition of a little nitrous acid. It scarcely unites with mercury by trituration. These properties seem to indicate, that the gold has so far received phlo-

General Effects of Heat.

110
This air extricated by part of the heat contained in the water.

111
Capacity of a body for containing heat, the same with the action of heat upon that body.

112
Impossibility of determining the quantity of heat any body contains.

113
Mr Nicholson's account of the capacities of bodies for containing heat, &c.

only question, therefore, which now remains is, By what means this air comes to be extricated, and to take up more room than it naturally does in the fluid? To this we can scarce give any other answer, than that part of the heat which is discharged from the freezing water combines with the air in its unelastic state, and, by restoring its elasticity, gives it that extraordinary force, as we see also in the case of air suddenly extricated in the explosion of gunpowder. Thus expansion, even in the case of freezing, is properly an effect of heat; and must therefore be considered as a phenomenon uniformly and certainly attending the action of heat, and in all cases to be ascribed to it.

The only way in which the element or fluid of fire can be supposed to act, and the way in which we can have a rational idea of its being able to produce both heat and cold according to the diversity of its action, has been already explained so fully, that it is needless at present to enter into any further discussion of the subject. It will easily appear, that the capacity for containing heat is nothing different from the action of heat upon that body in expanding, and at last altering its form in such a manner, as either to be able to insinuate itself among the particles in much greater quantity than before, still retaining its internal action, though the external one becomes imperceptible; or scattering them in such a manner, that it breaks forth in great quantity in its peculiar appearances of fire and light; in the former case producing vapour or smoke, and in the latter flame, as shall afterwards be more fully explained. It must likewise appear, that to determine the quantity of heat in any body is altogether impossible: and with regard to the lowest degree of heat, or a total expulsion of that fluid, so far from being able to determine what it is, the probability must be, that nature does not admit of any such thing; for if heat consists in the expansive action of a certain fluid, and cold in its opposite or contractile action, there is very little reason to suppose that the constitution of nature will allow any one of these actions entirely to cease, as it does not appear by what means it could again be renewed. Cold, as we have already seen, always tends to produce electricity; and the connection betwixt that and fire is so strong, that we cannot suppose the former to be carried to any great extreme without producing the latter. Whatever we may therefore suppose concerning the capacities of different bodies for containing heat, or concerning the point of total privation of heat, must be altogether void of foundation. A rule, however, has been given by Mr Kirwan for finding the point of total privation, which, together with its demonstration, we shall subjoin; and as it is necessary for the better understanding of this, to call to remembrance what has been said concerning the difference between the temperatures and specific heats of bodies, we shall insert an epitome of the doctrine from Mr Nicholson.

"If two equal bodies of different kinds and temperatures be brought into contact, the common temperature will seldom, if ever, be the mean betwixt the two original temperatures; that is to say, the surplus of heat in the hotter body will be unequally divided between them, and the proportions of this surplus retained by each body will express their respective dispositions, affinities, or capacities for heat.—If, there-

fore, a given substance, as for example fluid water, be taken as the standard of comparison, and its capacity for heat be called one, or unity, the respective capacities of their bodies may be determined by experiment, and expressed in numbers in the same manner as specific gravities usually are. And because it is established as well from reason as experiment, that the same capacity for heat obtains in all temperatures of a given body, so long as its state of solidity, fluidity, or vapour is not changed, it will follow, that the whole quantities of heat in equal bodies of a given temperature will be as those capacities. And as the respective quantities of matter, in bodies of equal volume, give the proportions of their specific gravities, so the respective quantities of heat in bodies of equal weight and temperature give the proportions of their specific heats.

"A greater capacity for heat, or greater specific heat, in a given body, answers the same purpose with respect to temperature as an increase of the mass; or the quantity of heat required to be added or subducted, in order to bring a body to a given temperature, will be as its capacity or specific heat.

"The capacities not only differ in various bodies, but also in the same body, according as it is either in a solid, fluid, or vaporous state. All the experiments hitherto made conspire to show, that the capacity, and consequently the specific heat, is greatest in the vaporous, less in the fluid, and least in the solid state.

"The quantity of heat that constitutes the difference between the several states, may be found in degrees of the thermometer. Thus, if equal quantities of water at 162° and ice at 32° of temperature be mixed, the ice melts, and the common temperature becomes 32° ; or otherwise, if equal quantities of frozen and fluid water, both at 23° , be placed in a like situation to acquire heat from a fire, the water will become heated to 162° , while the ice melts without acquiring any increase of temperature. In either case the ice acquires 130° of heat, which produces no other effect than rendering it fluid. Fluid water, therefore, contains not only as much more heat than ice, as is indicated by the thermometer, but also 130° , that is in some manner or other employed in giving it fluidity. And as fluid water cannot become ice without parting with 130° of heat besides what it had above 32° in its temperature; so also steam cannot become condensed into water without imparting much more heat to the matters it is cooled by, than water at the same temperature would have done.

"The heat employed in maintaining the fluid or vaporous form of a body, has been called latent heat, because it does not affect the thermometer.

"From the consideration of the specific heats of Mr Kirwan's theorem for finding the point of total privation of heat. the same body in the two states of fluidity and solidity, and the difference between those specific heats, is deduced a method of finding the number of degrees which denote the temperature of any body immediately after congelation, reckoned from the natural zero, or absolute privation of heat. The rule is; multiply the degrees of heat required to reduce any solid to a fluid state, by the number expressing the specific heat of the fluid: divide this product by the difference between the numbers expressing the specific heat of the body in each state; the quotient will be the number of

General Effects of Heat.

114

General Effects of Heat.

of degrees of temperature, reckoned from an absolute privation of heat.

"This theorem is Mr Kirwan's, and may be proved thus. Let s represent the required temperature of the body just congealed, l = the number of degrees that express the heat required to reduce it to fluidity, n = the specific heat of the solid, and m = the specific heat of the fluid. Then $s+l:s::m:n$. Whence

$$s = \frac{ln}{m-n} = \text{the temperature from the natural zero}$$

in thermometrical degrees of the fluid. But because the actual fall of the thermometer is to be produced by cooling the solid, must pay attention to its capacity. The quantity of heat required to produce a given change of temperature in a body is as its capacity; and consequently the changes of temperature, when the quantity of heat is given, will be inversely

as the capacities: therefore, $n:m::\frac{ln}{m-n}:\frac{ln}{m-n}=s$, which is the rule above mentioned.

"If the data l , m , and n , be accurately obtained by experiment, in any one instance, and the difference between the zero of Fahrenheit's scale and the natural zero be thence found in degrees of that scale, this difference will serve to reduce all temperatures to the numeration which commences at the natural o . So that s being known in all cases, if any two of the quantities l , m , or n , be given in any body, the other may be likewise had. For $l = \frac{sm-sn}{m}$; and $m = \frac{sn}{s-l}$ and $n = \frac{sm-lm}{s}$.

"To give an example of this curious rule, let it be required to determine how many degrees of refrigeration would absolutely deprive ice of all its heat? The degrees of heat necessary to melt ice are 130; and the specific heats of ice and water are as 9 to 10. The number 130 multiplied by 10, produces 1300, and divided by the difference between 9 and 10 quotes 1300: therefore if ice were cooled 1300 degrees below 32°, or to—1268 of Fahrenheit's scale, it would retain no more heat."

115
Fluidity to be ascribed to the absorption of heat.

II. *Fluidity* is another effect of heat, and is capable of taking place in all bodies hitherto known, when the fire is carried to a certain pitch. Theories have been invented, by which fluidity was ascribed to the smoothness and round figure of the particles whereof bodies were composed, and solidity to an angular or irregular figure. It has also been ascribed to a stronger degree of attraction between the parts of solids than of fluids. Dr Black, however, has shown, that in the case of melting ice, we are certainly to ascribe the acquired fluidity of the water to the absorption of heat. This was determined by a decisive experiment, in which he exposed a Florence-flask full of water to the atmosphere in a warm room, when he found that the heat in the air evidently left it, to flow into the ice in the bottle, and reduced it to fluidity. The air thus deprived of its heat, he felt sensibly descending like a cold blast from the bottle, and continuing to do so as long as any of the ice remained unthawed; yet after it was all melted, the temperature of the fluid was no more than 32°. Different degrees of heat are requisite for converting different solids into fluids, for which see the *Table of Degrees of HEAT*.

This theory receives an additional confirmation from the quantity of heat which is always known to be produced by the conversion of a fluid into a solid. And that this is really the case appears, 1. From what happens in the congelation of waters, it appears that ice is formed very slowly, and with several circumstances which support the theory.—Thus, if we expose equal quantities of water to the air, which is perhaps 10° below frost, and add to one of these a small quantity of salt or spirit of wine, and observe the cooling of each, we shall find them both grow gradually colder, until they arrive at the temperature of frost; after which the water containing the salt will continue to grow colder, until it has arrived at the temperature of the air, at the same time that only a small quantity of the other water is converted into ice. Yet were the common opinion just, it ought all to have been congealed by this time; instead of which, it is scarce grown a degree colder during the whole time. Its remaining at the same temperature for so long time, shows that it has been communicating heat to the atmosphere; for it is impossible that any body can remain in contact with another that is colder, without communicating heat to it. Whence then comes this heat? There must be some source adding to the sensible heat of the water, so as to keep up its temperature to the freezing point: and this source of heat must be very considerable; for it will continue to act for a very long time before the water is changed into ice; during all which time, even to the last drop, the water is not a degree colder than 32° of Fahrenheit's thermometer. This, therefore, is the *latent heat* of the water, which had formerly entered into it during its transition from ice to a fluid state.

A still stronger argument is derived from the following experiment; which evinces that the fluidity of water really depends upon its latent heat, and that the sensible heat is only a mean or condition to its containing the latent heat. This experiment consists in exposing water contained in a covered beer-glass to the air of a cold frosty night; and when the atmosphere is at the temperature of perhaps 10° or 12° below frost, the water will acquire that temperature without freezing: so that the fluidity of the water does not altogether depend on the quantity of sensible heat contained in it. The congelation, however, may be brought on by touching it with a bit of ice, with the extremity of a wire, by a shock upon the board, or otherwise disturbing it; and we then find the temperature suddenly raised up to 32°. This shows plainly, that the water has a disposition to retain the quantity of latent heat, upon which its fluidity must immediately and necessarily depend; and it retains it with a certain degree of force, so as to keep the water fluid in a temperature below that in which it usually parts with the latent heat and congeals. By disturbing it, however, we instantly bring on the congelation, which cannot take place without an extrication of the latent heat; which then, being changed into the ordinary or moveable heat, raises the thermometer as usual. The quantity of heat discharged from the first small portion of ice formed in the water is sufficient to prevent any more latent heat from separating, and consequently from any more ice being produced till more of the sensible heat is abstracted.

This doctrine extends not only to such bodies as are actually converted from a solid to a fluid; or from

General Effects of Heat.

117
Argument in support of the theory from water remaining fluid though cooled below 32°.

General Effects of Heat.

118 Heat the cause of the softness of bodies approaching to fluidity.

119 Absorption of heat the universal cause of fluidity.

120 Vapour formed by the absorption of latent heat.

121 Experiments by Dr Black on the conversion of water into vapour.

a fluid to a solid state, but to such as are in a kind of middle state betwixt solidity and fluidity; for every degree of softness depends on a certain degree of heat contained in the body. Thus, for instance, melted wax, allowed to cool slowly, soon becomes opaque and consistent; but it must be colder still before it attains its utmost degree of hardness. There is therefore a certain degree of heat below which every body is solid, and above which every one is fluid; the former being called the *congealing*, and the latter the *melting*, point of bodies.

By making experiments upon different substances, the Doctor was convinced that latent heat is the universal cause of fluidity; and the doctrine holds good in all the experiments that have hitherto been made upon spermaceti, bees-wax, and some of the metals. If they are melted, allowed to cool slowly, and a thermometer be immersed into them, we find, that as long as they continue fluid, their sensible heat diminishes very fast; but as soon as they begin to grow solid, the sensible heat continues greater than that of the air to which they are exposed; and during all this time it is communicating heat to the air, without having its sensible heat diminished: for the latent heat within the fluid gradually receives a sensible form, and keeps up the temperature, proving a source of sensible heat, which is communicated to the neighbouring bodies as well as the surrounding air. The softness and ductility of bodies depend on this also.

III. *Evaporation*. A third effect of the action of heat is that of converting bodies into vapour, by which they are rendered specifically lighter than the surrounding atmosphere, and enabled to rise in it. To account for this, many theories have been invented; but that of Dr Black, who accounts for it, as well as fluidity from the absorption of latent heat, is now universally received. The circumstances by which he proves and illustrates his doctrine are the following:

1. When we attend to the phenomena of boiling water, in a tea-kettle for instance, it may, when first put upon the fire, be about the temperature of 48° or 50° . In a quarter of an hour it will become heated to 212° . It then begins to boil, and has gained 162° of vapour in that time. Now, if the conversion of it into vapour depended on the quantity of sensible heat introduced, we may ask how long it will be necessary to raise it all in vapour? Surely another quarter of an hour should be sufficient; but this is far from being the case. Dr Black made some experiments upon this subject in conjunction with another gentleman. Having the opportunity of what is called a kitchen-table or a thick plate of cast iron, one end of which was made sensibly red-hot, they set upon this some iron vessels with circular flat bottoms, of about four inches diameter, and which contained a quantity of water. The temperature of the water was noted, as also when it began to boil; and when the whole of it was boiled away, it was found, that when set on the table its temperature had been 54° ; in four minutes it began to boil, and in that space of time received 158° degrees of heat. Had the evaporation, therefore, depended merely on the quantity of sensible heat introduced, it ought to have been dissipated entirely in a single minute more. It was, however, 18 minutes in dissipating; and therefore had received 807 degrees of heat before it was all evapo-

N^o 70.

rated. All this time, therefore, while the water continued to boil, it was receiving a great quantity of heat, which must have been flowing equally fast out of it; for the vessel was no hotter, and the iron plate continued equally hot, the whole time. The vessels were of different shapes, some of them cylindrical, some conical, others widening upwards; one of the designs of the experiment being to show how far the evaporation was retarded by the particular form of the vessels. By suspending a thermometer in the mouth of one of the evaporating vessels, the heat of the steam was found to be exactly 212° ; so that as the great quantity of heat absorbed was found neither to have remained in the water, nor to have been carried away by the steam in a sensible manner, we have nothing left to suppose, but that it flew off as one of the component parts of the steam in a latent state.

2. In an experiment to show the fixedness of the boiling point of water, Dr Black inclosed some of that fluid in a strong vial having a thermometer in it, and stopped close with a cork. By the application of heat he hoped now to be able to raise the thermometer some degrees above the boiling point, which would be the natural consequence of the confinement of the steam. When this was done, he pulled out the cork, and supposed that the water would now all fly out in vapour: but in this he was totally disappointed; a sudden and very tumultuous boiling ensued, which threw out some of the water; but though some quantity of steam likewise issued, the quantity of water was not considerably diminished. The vial had been heated to 20° above the boiling point, but almost instantly cooled down to 212° , when the cork was taken out.

3. Mr Watt, in making some experiments on the force of steam, had occasion to use Papin's digester, with a pipe proceeding from its side; the orifice of which was shut with a valve pressed down by one end of a lever. Thus he heated steam to 400° of Fahrenheit; after which, having suddenly struck off the lever, a quantity of steam flew out with considerable noise, and with such violence as to make an impression on the ceiling of the room; but this noise gradually diminished, and after ten minutes ceased entirely; and upon opening the machine, he found the greatest part of the water still remaining.

4. The change of sensible into latent heat in the formation of vapour, appears still more evident in the boiling of water *in vacuo*. Mr Boyle took a quantity of water which had been previously boiled to purge it of its air, and put it whilst hot under the receiver of an air-pump. In consequence of this it began again to boil, and continued boiling till it was only lukewarm, and it soon arrived at this temperature; so that in this case also the heat had disappeared during the conversion of the fluid into vapour. Others have repeated the experiment, as Boerhaave, Muschenbroek; and Robinson, who lectures on chemistry in Glasgow, says that the heat diminishes very fast till it comes to 90° or 95° , which seems to be the boiling point of water *in vacuo*. As a considerable part of the heat thus disappears, and is to be discovered neither in the water nor in the vapour, we must conclude that it enters the latter as part of its composition.

5. Thus also we may understand some curious experiments made by Dr Cullen upon ether and other volatile

General Effects of Heat.

122 Boiling point of water in *vacuo* determined by Mr Boyle.

123 And by Mr Robinson of Glasgow.

General Effects of Heat. 124
 Dr Cullen's experiments on cold produced by evaporation.
 volatile fluids. He employed some persons to make experiments upon the cold produced by evaporation; and willing to repeat them himself *in vacuo*, he put some of the most volatile liquors under the receiver of an air-pump. One of these was ether. It was contained in a glass, in which there was also placed some water. When the air was extracted, the ether began to boil, and to be converted into vapour, till it became so very cold that it froze the water contained in the vessel, though the temperature of the room was about 50° . Here therefore there was a quantity of heat which disappeared all of a sudden; which it is plain could not be owing to its having any communication with that of the atmosphere or other cold bodies, as they could not render it colder than they were themselves. Ether therefore is to be considered as a fluid so volatile, that were it not for the pressure of the atmosphere it would be perpetually in the state of vapour.

125
 Heat expelled in great quantity by the condensation of vapour.
 6. That this heat which enters into the vapour is not destroyed, but remains in a latent state, is easily proved; for we find that a great quantity of heat is expelled from vapour when it is condensed again to form the body it composed originally. This is easily ascertained by observing the quantity of heat communicated to the water in the refrigeratory of a still by any given quantity of liquid which comes over. Thus, if the refrigeratory contain 100 pounds of water, and the distillation be continued till only one pound has come over, supposing the water in the refrigeratory to have received 8° of heat; it is plain, that if the whole of the quantity thus received could be thrown into one pound of water, the latter would be heated to 800° ; which is sufficient to make an equal space of iron red-hot. But that this quantity of heat is received by the water in the refrigeratory has appeared from several experiments, which show that water, by being converted into vapour, absorbs between 800° and 900° of heat.

126
 Mr Watt's experiments on the evaporation of fluids in *vacuo*.
 On this principle we may explain some curious experiments made by Mr Watt with regard to the evaporation of fluids *in vacuo*. That gentleman had formed a design of converting water into steam with less expence of fuel, which he imagined might be done by removing the pressure of the air from the water, which he thought would thus require a much smaller quantity of fuel to convert it into vapour. Dr Black, however, perceiving that only the small quantity of sensible heat the steam possessed could thus be carried off, informed him beforehand that his project would not be found attended with the advantages he imagined. The experiment, however, was made in the following manner: A still was procured of tinned iron, the body of which resembled that of a retort, with a vessel serving as a condenser; the whole apparatus being close, excepting a little hole in the extremity of the condensing vessel. He first exhausted this vessel of air by holding the condenser over the retort, in which some boiling water was contained, until it was entirely converted into steam. He then suddenly stopped the little hole, and removed the vessels from the fire; when, after they were cooled, there was a pretty perfect vacuum formed by the condensation of the steam. The retort was then put on the fire, and turned so that the pipe and condensing vessel should

hang downward; and plunging them into cold water, heat was applied to the still till the water boiled, as could be known by the noise. It was kept boiling, till a quantity of steam was pushed over and condensed with a very gentle heat, the still feeling little warmer than his hand. After a certain quantity had been distilled, the apparatus was removed, and he had noted the heat of the water in the refrigeratory; but though the steam all along came over with so gentle a heat, he found the quantity communicated to the water in the refrigeratory to be surprisingly great, not less than 1000° ; so that it would have been more than sufficient to heat the quantity of liquor which came over red-hot.

127
 Ignition.
 IV. Ignition, or the causing bodies to shine or emit light in the dark. This may be considered as a species of inflammation, and shall therefore be explained under that head: here we shall only observe, that ignition is a more steady and constant effect of heat than either the production of fluidity or vapour; and appears not only to be the same degree with regard to any particular body, but the same with regard to all kinds of matter. Dr Martin imagines, that a red-hot piece of iron is hotter than a red-hot piece of stone; but if you put into a crucible an hundred different kinds of matter, as metals, glass, &c. that are capable of bearing a red heat, they will all begin to appear luminous about the same time, and their brightness will increase equally as their heat increases. But it is difficult to know at what point this begins, as we have no way of ascertaining the beginning or lowest degree of ignition but by the effect it produces on our sight, and we cannot be sure that we perceive the lowest degree of light; for we know that other animals see objects with such light as appears perfect darkness to us. Sir Isaac Newton's method of determining this has been already mentioned.

129
 Metals may become vastly hotter after they are brought into fusion.
 Dr Boerhaave entertained a notion, that some metals, after being once brought into a state of fusion, could be made no hotter; and proposes the possibility of this as a question, "Whether the heat of metals can be increased after they are melted?" There is not, however, the least doubt but that their heat may be vastly increased after they are melted; and we know certainly that such as are of easy fusion may be heated to a vastly greater degree after being melted; and why may not those requiring stronger heats be the same? We are sure that this is the case with silver, which, after being melted, may be brought to such a heat as to become too dazzling for the eye to bear it. If Boerhaave's opinion were just, it would be impossible to cast any metal into moulds, because it must lose a little heat in being removed from the fire and in entering the mould; nor would they receive a proper impression if they did not contain a greater quantity of heat than was necessary for their fusion.

130
 Ignition an universal effect of fire.
 Ignition appears to be universal; and all bodies capable of supporting it without being converted into an elastic vapour that cannot be confined, are affected the same way. Water, which in its ordinary state seems very little capable of enduring this heat, may be confined in strong vessels so as to become capable of melting lead, which is more than half way betwixt a red heat and that of boiling water. Experiments with the eolipile show also that it can be made red-hot; for when the steam passes through burning fuel, it can-

General
Effects of
Heat.

not miss of being made red-hot. Dr Black has also frequently seen the vapour of water heated by throwing it into the ash-pit of a furnace, so as to produce a very large and transparent flame in rising up through the vent. There is reason therefore to conclude, that ignition is one of the more general effects of heat, only that some bodies are incapable of it until they be reduced to a state of vapour.

132
Difference
betwixt ig-
nition and
inflammation.

V. The last of the effects of heat here to be taken notice of is *inflammation*. It differs from ignition in this, that the bodies subject to the latter gradually grow cooler as soon as they are taken out of the fire, without undergoing any considerable change; while those subject to inflammation become continually hotter and hotter, communicating a vast quantity of heat to others, and undergoing a kind of decomposition themselves, insomuch, that by this means they have been thought to be reduced to their constituent principles or elements. Some substances indeed seem to be an exception to this, as in the open air they burn totally away, without leaving any residuum or producing any soot. These are spirit of wine, sulphur, and especially inflammable air; which last, by a proper mixture with dephlogisticated air, may be so totally consumed, that scarce a fiftieth part of the two will remain. On a careful examination of these substances, however, we find that there is by no means a total consumption, or indeed, properly speaking, any consumption at all, at least if we measure the quantity of matter by the weight of the substance employed. Thus, if we are at pains to collect the vapour of burning spirit of wine, we will find, that an aqueous dew is collected, which sometimes equals the spirit of wine itself in weight. With regard to sulphur, the case is still more evident; for the vapour of this, when collected, not only equals but greatly exceeds the weight of the sulphur employed; and on burning dephlogisticated and inflammable air together, as much water is found to be produced as nearly equals the weight of both airs. In like manner, when we collect the ashes, water, soot, and oil, procured by burning any of the common inflammable substances, we will find, that they in general exceed the weight of the matter employed. The great waste of bodies by fire, therefore, is owing to the dissipation of the volatile principles they contain, which are carried off and rendered invisible by being mixed with the atmosphere.

ed weight
of metals
by calcina-
tion.

The process of inflammation has long been explained from the presence of a substance called *Phlogiston* in those bodies which are subject to it, and which is supposed to be the same in all bodies belonging to this class; the differences between them arising from the principles with which it is combined. This doctrine, which was first introduced by Stahl, has given occasion to such various and discordant theories, that the existence of phlogiston has been lately denied altogether by M. Lavoisier, who brought in a new method of solving the phenomena of fire, heat, and ignition, without any assistance from this principle. The foundation of M. Lavoisier's doctrine is the increase of weight in metals by calcination. This increase he finds to be precisely, or very nearly so, proportionable to the decrease of weight in the air in which they are calcined. His theory, therefore, is, that in the act of calcination, the pure part of the air,

which he calls the *acidifying* or *oxygenous* principle, unites with the metal, and converts it into a calx. In like manner, in substances truly inflammable, the heat and flame are supposed to proceed from the union of the pure air, or the oxygenous principle, with the substance, and converting it into those principles which are found to remain after inflammation. Thus the increased weight of the substance is easily accounted for; while the inflammation, in his opinion, is nothing more than a combination of the inflammable body itself with pure air, which has an attraction for it: and in confirmation of this it is urged, that when combustion is performed in empyreal or dephlogisticated air, the whole of the latter is absorbed; but in common atmospherical air only one fourth, being the quantity of pure air contained in it.

Other arguments in favour of this opinion are, that the calces of the perfect metals may be reduced without addition by the mere emission of the oxygenous principle, (dephlogisticated air); by an union with which they assume the form of a calx. Thus he evades a very strong argument used by the opposite party; who adduced, as a proof of the existence of phlogiston, the use of charcoal in the reduction of metals to their proper form. A dispute indeed took place betwixt M. Lavoisier and Dr Priestley concerning the reduction of the whole of a mercurial calx formed by an union with the nitrous acid without addition; the Doctor maintaining, that the whole could not be reduced by mere heat, but that a very perceptible quantity was always lost: but on a thorough examination of the subject, the truth seemed rather to lie on M. Lavoisier's side. See AEROLOGY.

Another theory, somewhat similar to that of Lavoisier's, has been published by Dr Lubbock, in an Inaugural Dissertation in 1784. In this he supposes two kinds of matter to exist in the universe; one he calls the *principium proprium*, the other the *principium forbile*; and it is this latter, which, according to our author, is the principle of mutability, or which, by being united in various proportions with the other, forms bodies of all the different kinds we see in nature. It is this principle, therefore, which he supposes to be absorbed in the calcination of metals, and not empyreal air, as M. Lavoisier supposes; and he contends, that this same principle extends throughout the whole system of nature, even to the utmost celestial bounds.

It would exceed the limits of this treatise to give an account of the various theories which have been invented, and the arguments used for and against them; nor indeed is there any occasion for doing so, as late experiments have reduced the dispute into a much narrower compass than before, and furnished the most decisive arguments in favour of the existence, of phlogiston.

The greatest objection to the belief of this principle was, that it could neither be seen nor felt by our senses directly, nor discover itself indirectly by the weight it communicated to the bodies with which it was united; on the contrary, the latter always became lighter in proportion to the quantity they contained: so that it was imagined, instead of being possessed of any specific gravity of its own, to be a principle of positive levity, such as that of heat or light may be reasonably supposed. This objection, however, is now entirely removed; and phlogiston in the abstract is found

found to be no subtle principle capable of eluding our researches, but one very common, and easily met with, being no other than common charcoal. In the last edition of this work, under the article PHLOGISTON, it was shown, that inflammable air, deprived of its elasticity, and combined with metallic substances, is really their phlogiston; and that in the inflammable bodies commonly used, what we call their phlogiston, is really their oil; and that which exists in charcoal, and cannot be driven off by distillation, is part of the empyreumatic or burnt oil of the subject which adheres so obstinately. A similar doctrine soon after appeared in the Philosophical Transactions for 1782, and the identity of phlogiston and inflammable air was clearly proved by Mr Kirwan. Still, however, it was insisted by the French philosophers and others, that no *facts* had been adduced against M. Lavoisier, nor any decisive proofs appeared of the existence of phlogiston as a substance *per se*. Facts of this kind, however, have now been discovered by Dr Priestley, and are related under the articles AEROLOGY, CHARCOAL, PHLOGISTON, &c. It is sufficient at present to mention, that he has been able to convert the purest spirit of wine, and one of the hardest metals, viz. copper, as well as several others, into a substance entirely resembling charcoal; that by means of the heat of a burning glass in vacuo, he has dissipated this metallic charcoal, as well as the common kind, *entirely* into inflammable air, with the assistance only of a little water, which seems necessary to make it assume the aerial form, and perhaps is the true solvent of it; and by a combination with the element of heat, with the aid of the charcoal, is enabled to resist condensation in the common way*. This inflammable air, when absorbed by metallic calces, again reduces them to their metallic form: so that here is one fact by which the phlogiston not only appears to our senses, but we are able to ascertain its quantity with the utmost precision. Nor can it here be any objection, that the reduced metal is lighter than the calx; for this only proves that the metallic earth, while a calx, is united to a heavy ingredient (the basis of dephlogisticated air), and in the latter to a light one, viz. charcoal, the basis of inflammable air.

Another case in which the existence of phlogiston is made equally evident to our senses, and where no such objection can occur, is related under the article AEROLOGY, n° 112. It is there shown, that "by the loss of one grain of charcoal of copper (formed by the union of spirit of wine with the metal), and which like common charcoal was consumed without having any residuum, he reduced four ounce-measures of dephlogisticated air till only one-ninth remained unabsorbed by water; and, again, with the loss of one grain and a half of charcoal, six and an half measures of dephlogisticated air were reduced till five and an half measures were pure fixed air."—Here, then, is an absolute and undeniable evidence, that fixed air is composed of dephlogisticated air, and charcoal or phlogiston, and elementary fire. There were no other ingredients present, and the charcoal must either have been annihilated or disposed of in the manner just mentioned: but the superior weight of the fixed air evidently shows that some ingredient had been added to the dephlogisticated air; and which increase was more than we can

suppose to arise from the condensation of the dephlogisticated air during the operation, for this sometimes amounted to no more than one-thirtieth part.

The strongest objection which can be made against the doctrine of phlogiston may be drawn from the total consumption of pure air in certain cases of combustion, for instance, in that of phosphorus, inflammable air, and iron. It must be observed, however, that in no case whatever is the air totally consumed; and in that of inflammable air water is produced by the union of the basis of the latter, that is charcoal, with the basis of dephlogisticated air, the oxygenous principle of M. Lavoisier, and which appears to be one of the component parts of WATER. In the case of phosphorus, the latter is converted into an acid; and in all probability a quantity of water is also produced, by which part of it is converted into crystalline flowers. The case of the iron, therefore, alone remains to be considered. Dr Priestley's experiments on this subject are related at length under the article AEROLOGY, n° 67 *et seq.* In them the iron burnt briskly in dephlogisticated air, which, according to the common theory, should have indicated the expulsion of a great quantity of phlogiston; yet the whole residuum, of which the fixed air, produced by the supposed union of the phlogiston or principle of inflammability, was only a part, scarce amounted sometimes to one-fourteenth of the air originally employed.

This argument, however, instead of contradicting the existence of phlogiston, only shows, that in some cases the dissipation of a very small quantity of phlogiston is necessary to inflammation; or that the aerial principle may combine with the iron in its metallic state. In this case only a very little quantity of the phlogiston of the iron was dissipated; for it was not reduced to a calx, but to that kind of scoriae which flies off in scales by beating the metal when red-hot with an hammer. A decisive proof of this was had by uniting iron thus combined with the basis of dephlogisticated air with inflammable air. By this the metal was indeed reduced to perfect iron again; but water was produced at the same time from the union of the basis of the two airs, that of the inflammable air being capable of furnishing a superfluous quantity, which united with the other into the form of a fluid.

The existence of phlogiston being thus proved, and its nature ascertained, we may now proceed to determine the question, Whether the great quantity of heat produced by the combustion of inflammable bodies proceeds from the bodies themselves, or from the air which must be admitted to them in order to make them burn? That the heat in this case proceeds from the atmosphere is evident; because in all cases of combustion there is a certain diminution undoubtedly takes place by means of the conversion of the dephlogisticated part of the atmosphere into fixed air. It is proved, under the article *ELASTIC Vapours*, that elementary fire is the universal cause of elasticity in fluids. By uniting a certain quantity of it with any substance, the latter at length assumes an aerial or vaporous form; and it is this vapour alone which is inflammable*. Different vapours no doubt contain different quantities of these ingredients; but in all cases the basis of the dephlogisticated part of the atmosphere

must unite with the phlogiston of the inflammable body, or with something else, so that a decomposition may ensue: and it is this decomposition which produces the heat and light; for then the fire contained in the atmosphere having no longer any thing to absorb it, must appear in its proper form. But in those cases where there is a great quantity of phlogiston, and consequently much fixed air produced, the latter absorbs so much heat in a latent state, that the quantity communicated to surrounding bodies must be greatly diminished; and if by an excess of this ingredient, not only fixed air, but the phlogisticated kind and gross smoke be also produced, this diminishes the heat still farther by the great absorption, and will even destroy it altogether. The remedy for this is either to diminish the quantity of phlogiston, or to augment the quantity of air; which, by furnishing a greater quantity of dephlogisticated basis, affords an opportunity for the evolution of a greater quantity of heat. On the other hand, when the quantity of air is too great, the phlogistic matter cannot combine with the basis of the pure air in sufficient quantity to effect a decomposition; and therefore the heat is absorbed in a latent state, and the fire goes out.

From this theory, which is further illustrated under the articles FIRE, FLAME, HEAT, PHLOGISTON, &c. we may not only have a rational idea of the manner in which inflammation is generally accomplished, but see why a fire may be put out both by too great a quantity of fuel, and by too great a quantity of air. We may also see why the solar beams and electric fluid, which contain no phlogistic matter, excite a much more powerful heat than any we can raise in our hottest furnaces. The difference between ignition and inflammation will now likewise appear; such bodies as are capable only of ignition containing little or no phlogiston, but inflammable bodies a great deal.

The following table shows the most remarkable degrees of heat from the congelation of mercury to that of Mr Wedgewood's hottest furnace.

Elective
Attraction.

SECT. II. Of the Doctrine of Elective Attraction, and of the different Objects of Chemistry.

BEFORE we proceed to give a general theory of the changes which happen upon the mixtures of different bodies together, or exposing them singly to heat, we must observe, that all depend on certain qualities in bodies, by which some of them are apt to join together, and to remain united while they have an opportunity. The cause of these qualities is totally unknown; and therefore philosophers, after the example of Sir Isaac Newton, have expressed the apparent effect of this unknown cause by the word *attraction*. From them the word has been adopted by the chemists, and is now generally used in speaking of the phenomena which are observed in the mixture of different substances; but to distinguish it from other kinds, it is usually called *Elective*.

This attraction is not equally strong between all substances; in consequence of which, if any body is compounded of two others, and another is presented to it which has a greater attraction for one of the component parts than they have for one another, the substance will be *decompounded*. A new compound is then formed by the union of that third substance with one of the component parts or *elements* (if we please to call them so) of the first. If the attraction between the body superadded and either of the component parts of the other is not so strong as that between themselves, no decomposition will ensue; or if the third substance is attracted by both the others, a new composition will take place by the union of all the three.

The objects of chemistry, as we have already observed, are so various, that an enumeration of them all is impossible. To ease the mind, therefore, when speaking of them, and render more useful any thing that is said or wrote on chemistry, it is necessary to divide them into different classes, comprehending in each class those bodies which have the greatest resemblance to one another, and to which one common rule applies pretty generally.—The division formerly used, was that of vegetables, animals, and minerals; but this has been thought improper, as there are many substances in each of those kingdoms which differ very widely from one another, and which are by no means subject to the same laws. The most approved method,

chemistry
how clas-
sed.

^{Salts.} thod, at present, of arranging the objects of chemistry, is into salts, earths, metals, inflammable substances, waters, animal and vegetable substances.

SECT III. *Salts.*

¹⁶⁴
Salts.

SALTS are either *fusible*, that is, capable of abiding the fire, and melting in a strong heat, without being dissipated; or *volatile*, that is, being dispersed in vapour with a small heat. Their other properties are; that they are soluble in water; not inflammable, unless by certain additions; and give a sensation of taste when applied to the tongue.

The most general characteristic of salts is, that they are all soluble in water, though some of them with much more difficulty than others. Most of them have likewise the property of forming themselves, in certain circumstances, into solid transparent masses of regular figures, different according to the different salt made use of, and which are termed *crystals* of that salt. In this state they always contain a quantity of water; and therefore the utmost degree of purity in which a salt can be procured, is when it has been well crystallized, and the crystals are freed of their superfluous moisture by a gentle heat. They generally appear then in the form of a white powder.

¹⁶⁵
Phenomena attending their solution.

In the solution of salts in water, the first thing observable is, that the water parts with the air contained in it; which immediately rises to the top in the form of bubbles. This, however, is most remarkable when the salt is in the dry form we have just now mentioned, because there is always a quantity of air entangled among the interstices of the powder, which rises along with the rest; and this discharge of air is sometimes so great, as to be mistaken for an effervescence. From this, however, it is essentially different. See EFFERVESCENCE.

Another thing observable in the solution of salts is, that a considerable change happens in the temperature of the water in which they are dissolved; the mixture becoming either a good deal warmer or colder than either the salt or the water were before. In general, however, there is an increase of cold, and scarce any salt produces heat, except when it has been made very dry, and deprived of that moisture which it naturally requires; and thus the heating of salts by being mixed with water may be explained on the same principle with the heat produced by quicklime. See QUICKLIME.

After salt has been dissolved in a certain quantity by water, no more of that salt will be taken up unless the water is heated; and as long as the heat continues to increase, the salt will be dissolved. When the water boils, at which time it has attained its greatest heat, and will take up no more salt, it is then said to be *saturated* with that salt. This, however, does not prevent it from taking up a certain quantity of another salt, and after that perhaps of a third, or fourth, without letting go any of the first which it had dissolved. How far this property of water extends, has not yet been ascertained by experiments.

To the above rule there is only one exception known as yet; namely, common sea-salt: for water dissolves it in the very same quantity when cold as when boiling hot. It has been said by some, that all deliquescent salts, or those which grow moist on being

exposed to the air, had the same property: but this is found to be a mistake.

This property of solubility, which all the salts possess in common, renders them easily miscible together; and the property by which most of them shoot into crystals, renders those easily separable again which have no particular attraction for one another. This is likewise rendered still more easy by their requiring different proportions of water, and different degrees of heat, to suspend them; for by this they crystallize at different times, and we have not the trouble of picking the crystals of one out among those of the other.

The manner in which the solution of salts in water is effected, is equally unaccountable with most of the other operations of nature. Sir Isaac Newton supposed that the particles of water got between those of the salt, and arranged them all at an equal distance from one another: and from this he also accounts for the regular figures they assume on passing into a crystalline form; because, having been once arranged in an orderly manner, they could not come together in disorder, unless something was to disturb the water in which they were suspended; and if any such disturbance is given, we find the crystals are by no means so regular as otherwise they would have proved. Others have thought that these figures depend on a certain *polarity* in the very small particles into which the salt is resolved when in a state of solution. These things, however, are merely conjectural; neither is it a matter of any consequence to a chemist whether they are right or wrong.

Though solution is that operation which salts undergo the most easily, and which should seem to affect them the least of any, a repetition of it proves nevertheless very injurious to them, especially if it is followed by quick evaporation; and the salt, instead of being crystallized, is dried with a pretty strong heat. Newman relates, that a pound of sea-salt was reduced, by 13 solutions and exsiccations, to half an ounce; and even that was mostly earth. Where solution is required, therefore, it ought always to be done in close vessels, in which also the subsequent evaporation should be performed, (see EVAPORATION); and in all cases where crystallization is practicable, it ought to be preferred to violent exsiccation.

The two great divisions of salts are into acids and alkalies. The former of these are known by their peculiar taste, which is called *acid* or *sour*. They are not found in a solid form; neither are any of them, except the acids of vitriol, of tartar, of phosphorus, and of borax, capable of being reduced to solidity. The others, when highly concentrated, that is, brought to the utmost degree of strength of which they are capable, always become an invisible vapour, permanently elastic, until it comes in contact with water, or some other substance with which they are capable of uniting. For such acids the name of *salts* seems less proper, as we can scarcely say that a *vapour*, which is already much more fluid than water, can be *dissolved* in that element.

The acids are divided into the mineral, the vegetable, and the animal; expressing their different origin, or where they are most commonly to be found. The mineral acids are commonly reckoned three; the

Acids.

vis-

Salts.

vitriolic, the nitrous, and the marine. To this the acid of borax ought to be added; but its weakness makes it much less taken notice of as an acid than the others. A Swedish chemist, however, Mr Scheele, hath lately added several others, which are afterwards taken notice of.

The vegetable kingdom affords only two distinct species of acids, at least without the assistance of some chemical operation. The one appears fluid, and when concentrated to the utmost degree becomes an invisible vapour. This is produced from fermented liquors, under the name of *vinegar*. An acid similar to this, and which is thought not to be essentially different from it, is extracted from most vegetables by distillation with a strong fire. The other is likewise a consequence of fermentation; and crusts on the bottom and sides of casks in which wine is put to depurate itself. In its crude state it is called *tartar*; and when afterwards purified, is called the *cream*, or crystals, of tartar. As for the various acids produced in the different chemical processes to be afterwards related, we forbear to mention them at present, it being justly suspected that some of them are artificial.

The animal acids, which have hitherto been discovered, are only two; the acid of ants, and that of urine, which is also the acid of phosphorus. The first of these is volatile; and consequently must be supposed a vapour when in its strongest state: the other is exceedingly fixed; and will rather melt into glass than rise in vapours. Besides these, it is said an acid is contained in blood, in wasps, bees, &c.: but no experiments have as yet been made on these to determine this matter with any degree of precision.

170
Alkalies.

The alkalies are of two kinds; fixed and volatile. The fixed kind are subdivided into two; the vegetable, and mineral or fossil alkali. The vegetable is so called, because it is procured from the ashes of burnt vegetables; the fossil, because it is found native in some places of the earth, and is the basis of sea-salt, which in some places is dug out of mines in vast quantity. They are called *fixed*, because they endure a very intense degree of heat without being dissipated in vapour, so as even to form a part of the composition of glass. The volatile alkali is generally obtained by distillation from animal substances. In its pure state this alkali is perfectly invisible; but affects the sense of smelling to such a degree, as not to be approached with safety.

171
Different
action of
alkalies and
acids.

The acids and alkalies are generally thought to be entirely opposite in their natures to one another. Some, however, imagine them to be extremely similar, and to be as it were parts of one substance violently taken from each other. Certain it is, that when separated, they appear as opposite to one another as heat and cold. Their opposite action indeed very much resembles that of heat and cold, even when applied to the tongue; for the alkali has a hot, bitter, burning taste, while the acid, if not considerably concentrated, always gives a sensation of coldness. In their action too upon animal substances, the alkali dissolves, and reduces the part to a mucilage; while the acid, if not very much concentrated, tends to preserve it uncorrupted.

172
Neutral
salts.

If an alkaline salt, and moderately strong acid in a liquid state, be mixed together, they will immediately

unite; and, provided the alkali has not been deprived of its fixed air, their union will be attended with a very considerable effervescence: (see AEROLOGY.) If the alkali has been deprived of air, no effervescence will ensue, but they will quietly mix together; but if a due proportion of each has been added, the liquor will neither have the properties of an acid nor an alkali, but will be what is called *neutral*. The bringing the liquor into this state, is called *saturating* the acid or alkali, or combining them to the point of saturation.

If the liquor after such a saturation be gently evaporated, a saline mass will be left, which is neither an acid nor an alkali, but a new compound formed by the union of the two, and which is called a *perfect neutral salt*. The epithet *perfect* is given it, to make a distinction between the salts formed by the union of an acid and an alkali, and those formed by the union of acids with earthy or metallic substances; for these will likewise unite with acids, and some of the compounds will crystallize into regular figures; but, because of their weaker union with these substances, the salts resulting from combinations of this kind are called *imperfect*.

All acids, the volatile sulphureous one excepted, change the blue infusions of vegetables, such as violets, to a red; and alkalies, as well as some of the imperfect neutrals, change them to green. This is the nicest test of an acid or alkali abounding in any substance, and seems the most proper method of determining whether a solution intended to be neutral really is so or not.

173
Vegetable
colours
changed by
acids and
alkalies.

Though between every acid and alkali there is a very strong attraction, yet this is far from being the same in all; neither is it the same between the same acid and alkali in different circumstances of the acid. When the acids are in a liquid state, and as free as possible of inflammable matter, between which and the nitrous and vitriolic acids there is a very strong attraction, the vitriolic will expel any of the rest from an alkaline basis, and take its place. Thus, if you combine the acid of sea-salt, or marine acid, to the point of saturation, with the fossil alkali, a neutral salt will be formed, which has every property of common salt: but, if you pour on a certain proportion of the vitriolic acid, the acid of sea-salt will immediately be expelled; and the liquor, upon being evaporated, will contain not the neutral salt formed by an union of the marine acid with the alkali, but another consisting of the vitriolic acid joined with that alkali, and which has quite different properties from the former.

174
Differences
in the de-
grees of at-
traction be-
tween acids
and alkalies.

When the acids and alkalies are applied to one another in a liquid state, the vitriolic acid always shows itself to be the most powerful; but when applied in a solid form, and urged with a violent heat, the case is very much altered. Thus, the acid of borax, commonly called *sal sedativus*, is so weak as to be disengaged from its basis by every acid applied in a liquid form, that of tartar alone excepted; but if even the vitriolic acid combined with an alkali be mixed with this weak acid, then exsiccated, and at last urged with a vehement fire, the vitriolic acid will be disengaged from its basis, and rise in vapours, leaving the weaker acid in possession of the alkali. The same thing happens on adding the phosphoric or urinous acid,

^{Salts.} acid, or the acid of arsenic, &c. to combinations of the vitriolic or other acids with alkaline salts.—When the acids are in a liquid state, therefore the most powerful is the vitriolic; next the nitrous; then the marine; then vinegar; acid of ants; and lastly the sal sedativus and tartar, which seem to be nearly equal in this respect.—If they are applied in a solid form, the most powerful are the sal sedativus and phosphorine acid; then the vitriolic, nitrous, marine, and vegetable acids.

When they are reduced to vapour, the case is exceedingly different; for then the marine acid appears to be the most powerful, and the vitriolic the least so of any. It is impossible, however, to preserve the vitriolic acid in the form of vapour, without combining it with a certain quantity of inflammable matter, which must necessarily destroy its strength. Dr Priestley found, that the marine acid, when reduced to vapour, was capable of disuniting the nitrous acid from a fixed alkali.

Though the vitriolic acid sometimes assumes a solid form, it is by no means easy to reduce it to this state by mere concentration, without the assistance of nitrous acid. Baldasart, however, pretends that he discovered, in the neighbourhood of a volcano, a pure and icy oil of vitriol, from which nothing could be precipitated by alkaline salts; though there is certainly very great reason to doubt the accuracy of this observation. Of late the nitrous acid has also been found capable of assuming a solid form. This was first observed by M. Bernhard in distilling a very large quantity of the acid. At that time he perceived a white salt adhering to the inside of the receiver, which on examination proved to be the acid of nitre in a concrete form; being extremely corrosive, emitting red vapours copiously on being exposed to the air, and at length totally evaporating in it. Its specific gravity, however, was far inferior to that of the glacial oil of vitriol.

¹⁷⁵
Acids unite
with phlo-
giston.

The acids have the property of uniting themselves to many other substances besides fixed alkalies, and forming neutral compounds with them. Of these the chief is the principle of inflammability or phlogiston. In the vitriolic, nitrous, and phosphorine acids, the attraction for this principle is very strong; so great, that the two former will even leave a fixed alkali to unite with it. In the marine acid it is less perceptible; in the liquid vegetable or animal acid still less; and in the acid of tartar, and sal sedativus, not at all.

¹⁷⁶
With me-
tals and
earth.

Besides this, all acids will dissolve metallic and earthy substances: with these, however, they do not in general unite so firmly with alkaline salts; nor do they unite so strongly with metals as with earths.

¹⁷⁷
Electric
attractions

In general, therefore, we may expect, that after having dissolved a metal in any acid whatever, if we add an earthy substance to that solution, the acid will quit the metal, which it had before dissolved, to unite with the earth. In this case the solution will not be clear as before, but will remain muddy, and a quantity of powder will fall to the bottom. This powder is the metalline substance itself, but deprived of one of its component parts; and in this case it is said to *precipitate* in the form of a *calx*.

If to this new solution of the earthy substance in an acid liquor, a volatile alkaline salt, not deprived of its

fixed air, is added, the acid will quit the earth, and unite with the alkaline salt. The earth thus disengaged will again *precipitate*, and lie at the bottom in fine powder, while the volatile alkali and acid remain combined together, and the liquor again becomes clear.

The attraction between volatile alkalies and acids is considerably less than between fixed alkalies and the same acids. If, therefore, a fixed alkali be now added to the liquor, the volatile alkali will be separated, and the acid will unite with the fixed alkali. The volatile alkali indeed, being perfectly soluble in water, cannot precipitate, but will discover its separation by the pungent smell of the mixture; and upon evaporating the liquor, the volatile alkali will be dissipated, and a saline mass, consisting of the acid and fixed alkali, will remain.

Lastly, If the acid employed was the nitrous, which has a strong attraction for the principle of inflammability, if the saline mass be mixed with a proper quantity of inflammable matter, and exposed to a strong heat, the acid will leave the alkali with vast rapidity, combine with the inflammable matter, and be destroyed in flame in a moment, leaving the alkali quite pure.

Though the above-mentioned effects generally happen, yet we are not to expect that they will invariably prove the same whatever acid is made use of; or even that they will be the same in all possible variety of circumstances in which the same acid can be used.—The acid of tartar is one exception, where the general rule is in a manner reversed; for this acid will quit a fixed alkali for an earth, especially if calcined, and even for iron. If lead, mercury, or silver, are dissolved in the nitrous acid, and a small quantity of the marine acid is added, it will separate the stronger nitrous acid, and fall to the bottom with the metals in form of a white powder.—The vitriolic acid, by itself, has a greater attraction for earthy substances than for metals; and greater still for fixed alkaline salts than for either of these: but if quicksilver is dissolved in the nitrous acid, and this solution is poured into a combination of vitriolic acid with fixed alkali, the vitriolic acid will quit the alkali to unite with the quicksilver. Yet quicksilver by itself cannot easily be united with this acid. The reason of all these anomalies, however, is fully explained in the following section.

§ 1. Of the Operations of Solution and Precipitation.

THE chemical solution of solid bodies in acid or other menstrua, is a phenomenon which, though our familiarity with it has now taken off our surprise, must undoubtedly have occasioned the greatest admiration and astonishment in those who first observed it. It would far exceed the limits of this treatise to speak particularly of all the various circumstances attending the solution of different substances in every possible menstruum. The following are the most remarkable, collected from Mr Bergman's Dissertation on Metallic Precipitates.

1. On putting a small piece of metal into any acid, it is dissolved sometimes with violence, sometimes gently, according to the nature of the menstruum and of the metal to be dissolved.

2. The nitrous acid is the most powerful in its action.

Solution and Precipitation.

181

Nitrous acid the most violent in its operation.

tion upon metallic substances, when unassisted by heat. So great indeed is the violence with which this acid sometimes acts, that the metal, instead of being dissolved, separates instantaneously from it in the form of a calx or powder scarce soluble in any menstruum, at the same time that the heat, effervescence, and noxious vapours issuing from the mixture, render it absolutely necessary to moderate the action of the menstruum, either by dilution or cold, or both. In other cases, however, as when put to gold or platina, the nitrous acid has no effect until it be united with the marine, when the mixture acts upon those metals, which neither of the acids singly would touch.

182

Vitriolic acid acts more weakly.

3. The action of the vitriolic acid, though in the highest degree of concentration, is more weak. It does not readily attack silver or mercury unless assisted by a boiling heat, nor will even that be sufficient to make it act upon gold or platina.

183

Marine acid generally more weak than either, except when dephlogisticated.

4. The action of marine acid, unless on some particular substances, is still more weak; but when dephlogisticated, or deprived of part of the phlogiston essential to its constitution as an acid, it acts much more powerfully, and dissolves all the metals completely.

184

The rest of the acids much weaker still.

5. The other acids, as those of fluor, borax, with such as are obtained from the animal and vegetable kingdoms, are much inferior in their powers as solvents, unless in very few instances.

185

Different degrees of solubility in metals.

6. Metals vary very much in their degrees of solubility; some yielding to almost every menstruum, and others, as has been already observed, being scarce acted upon by the most powerful.

186

Solution sometimes promoted by abstracting a certain proportion of phlogiston.

6. Zinc and iron are of the former kind, and gold and silver of the latter, eluding the marine; and gold, unless in one particular case, viz. when assisted by heat in a close vessel, the action of the nitrous acid also. These metals, however, which in their perfect state resist the action of the most powerful menstrua, may be dissolved much more readily when deprived of a certain quantity of their inflammable principle. But though the separation of this principle in some degree renders metals more soluble, the abstraction of too much of it, particularly in the case of iron and tin, renders these metals almost entirely insoluble. Manganese is the most remarkable instance of this power of the phlogistic principle, in depriving metals of their solubility by its absence, or restoring it to them by its presence; for this substance, when reduced to blackness, cannot be dissolved by any acid without the addition of some inflammable matter; but when by the addition of phlogiston it has become white, may be dissolved in any acid.

188

Solution of metals attended with an effervescence.

7. The dissolution of metals by acids, even to their very last particle, is attended by a visible effervescence: this is more perceptible according to the quickness of the solution; but more obscure, and scarcely to be seen at all, when the solution proceeds slowly.

189

Various kinds of elastic fluids extricated.

8. The elastic fluids extricated by these solutions are various, according to the nature of the acid and of the metal employed. With the nitrous, the fluid produced is commonly that called *nitrous air*; with vitriolic and marine acids the produce is sometimes inflammable air, sometimes otherwise, according to the nature of the metal acted upon.

9. Heat in a greater or smaller degree is always produced during the dissolution of metals; and the de-

No 70.

6

gree of it is in proportion to the quantity of the matter and the quickness of the solution; and hence, in small quantities of metal, and when the solution proceeds very slowly, the temperature of the mass is scarcely altered.

10. The calces of metals either yield no air at all, or only the aerial acid, unless when urged by a violent heat almost to ignition; when, by means of vitriolic or nitrous acid, they yield a quantity of pure air, after other elastic fluids, such as vitriolic, nitrous, or phlogisticated air. None of the dephlogisticated air is usually produced by the marine acid in conjunction with metallic calces.

11. The solutions of some metals are coloured, others are not. The colour of the former is only that which is proper to the calx, but rendered more vivid by the moisture. Thus solutions of gold and platina are yellow; those of copper, blue or green; solutions of nickel of a bright green; but those of cobalt are red, although the calx is black. We may observe that even this red colour may be heightened to blackness. Iron moderately calcined is green; but this rarely continues upon further dephlogistication. The white calces of silver, lead, tin, bismuth, arsenic, antimony, and manganese, are dissolved without colour; but solutions of lead, tin, and antimony, are somewhat yellow, unless sufficiently diluted. Mercury, however, forms a singular exception to this rule; for the orange-coloured calx of this metal forms a colourless solution. The metals yielding coloured solutions are gold, platina, copper, iron, tin, nickel, and cobalt; the rest, if properly depurated, give no tinge. A solution of silver is sometimes of a blue or green colour at first, although there be no copper present; the vitriolic acid becomes blue with copper; the nitrous may be made either blue or green at pleasure; the marine varies according to the quantity of water with which it is diluted. Manganese, when too much dephlogisticated, renders both the vitriolic and marine acids purple.

With regard to the cause of chemical solutions, our author observes, that though attraction must be looked upon as the fundamental cause, yet we may also lay it down as a maxim, that no metal can be taken up by an acid, and at the same time preserve the whole quantity of phlogiston which was necessary to it in its metallic state. A certain proportion of the principle of inflammability therefore may be considered as an obstacle which must be removed before a solution can take place. Thus, of all the acids, the nitrous attracts phlogiston the most powerfully, and separates it even from the vitriolic. A proof of this may be had by de-boiling sulphur slowly in concentrated nitrous acid. At length all its phlogiston may be separated, and the vitriolic acid will remain, deprived of its principle of inflammability. The extraordinary solvent powers of this acid, therefore, is conformed to the peculiarity of its nature in this respect. For this menstruum dissolves metals for solution with the greatest ease, most commonly without any assistance from external heat; which in some instances would be hurtful, by separating too much of phlogiston, as appears in the case of iron, tin, and antimony; all of which may be so far dephlogisticated by the nitrous acid, as to be rendered extremely difficult of solution: for this reason it is very often necessary, as has already been observed, to temper the

activity of this menstruum by water. The vitriolic acid requires a boiling heat before it can act upon silver or mercury. The reason of this is, that by means of the heat, the watery part of the menstruum is diminished, its power is thereby increased, and the connection of the metallic earths with the inflammable principle diminished. Marine acid, which contains phlogiston as one of its constituent principles, must necessarily have little or no effect on those metals which retain their principle of inflammability very obstinately. But its watery part being diminished by boiling, it assumes an aerial form, and powerfully attracts a larger quantity of phlogiston than before; so that in a vaporous state it will dissolve metals, particularly silver and mercury, which in its liquid form it would scarce be brought to touch. When dephlogisticated as much as possible, it attracts phlogiston with prodigious avidity, dissolving all metals by its attraction for their phlogiston, and, uniting the inflammable principle to itself, resumes the ordinary form of marine acid. When dephlogisticated by means of nitrous acid in aqua regis, it dissolves gold and platina. On the same principles may we account for its inferiority in power to the other acids.

It has already been observed that the metals differ much in their degrees of solubility, which is owing to the various degrees of force with which they retain their phlogiston. Those called perfect metals effectually resist calcination in the dry way. In this operation, the fire on the one hand, the great cause of the volatility of bodies, strenuously endeavours to expel the phlogiston; on the other hand, the basis of the dephlogisticated part of the atmosphere (the acidifying principle of M. Lavoisier, and the *principium forbile* of Dr Lubbock) attracts the calx strongly. Experience, however, shows, that these two forces united, cannot decompose gold, silver, or platina to any considerable degree. All the other metals yield to these forces when united, but not singly. Iron and zinc retain their inflammable principle so slightly, that any acid immediately acts upon them; but if the other metals be properly prepared for solution by being calcined to a certain degree, the acid will immediately take them up. Any further privation, however, would be injurious, and precipitate what was before dissolved. Thus the nitrous acid, when added to a solution of tin or antimony in marine acid, by its extraordinary attraction for phlogiston carries off such a quantity of it, that the calces of the metals are immediately precipitated.

The various elastic fluids which resemble air, and which are produced in plenty during the dissolution of metals, may be reduced to the following, *viz.* those excited by the vitriolic, nitrous, and marine acids, fluor acid, vinegar, alkaline salts, and hepar sulphuris.

Pure vitriolic acid exposed to a violent heat, is indeed resolved into vapours, but of such a nature, that when the heat is gone, they condense again into an acid liquor of the same nature as before. But if any substance be added which contains phlogiston in a separable state, an elastic fluid is produced by means of fire, which is scarcely condensable by the most extreme cold, unless it comes in contact with water. This is called the volatile sulphureous acid, or vitriolic acid air, which may be totally absorbed by water. In this case the bond of union betwixt it and the phlogiston

is so weak, that the latter soon flies off totally, and common vitriolic acid is regenerated.

The nitrous acid undergoes a similar change in a more obvious manner. Let a piece of silver, for instance, be put into a dilute nitrous acid, and the surface of the metal will instantly be covered with innumerable bubbles, which arising to the top of the liquor, there burst; and if collected, are found to be nitrous air. The nitrous acid saturates itself with phlogiston more completely than the vitriolic; therefore the elastic fluid produced, or nitrous air, does not unite with water, and scarce retains any vestige of an acid nature. The vitriolic acid, however, differs from the nitrous in this respect, that the phlogiston is absorbed by the latter even beyond the point necessary to obliterate its acid nature. In proof of this, our author adduces the decomposition of hepatic by means of nitrous air.

The marine acid exhibits different phenomena. It naturally contains phlogiston, and therefore can by its means be resolved into a kind of air somewhat similar to that produced by the vitriolic acid when artificially united to the same principle, and which has the same property, *viz.* that of remaining permanently elastic as long as it is kept from the contact of water. But as the acid we speak of naturally contains phlogiston, there is no necessity of adding more to produce this effect. In the mean time, the marine as well as nitrous air, when in its expanded state, attracts phlogiston, and that with wonderful avidity.

When the marine acid is dephlogisticated, it yields another elastic fluid of a reddish brown colour, having an odour like that of warm aqua regia. This does not unite with water, or only in very small quantity; and by the addition of a proper proportion of phlogiston may be reduced again to common marine acid. It is said that the marine acid may be dephlogisticated by lead as well as by manganese, the nitrous acid, and arsenic.

The fluor acid abounds with phlogiston, and therefore may, without any adventitious matter, be reduced to an elastic fluid. This air is easily distinguished from all others by its corrosion of glass whilst hot.

Vinegar also contains phlogiston; and for that reason, when well dephlegmated, may be reduced without addition into a permanently elastic fluid, called acetous air.

All these fluids seem to be nothing else, according to Mr Bergman, than the acids themselves expanded by phlogiston. "Perhaps (says he) the matter of heat also enters their composition." The experiments lately made on these subjects, however, have put it beyond all doubt, that the expansive principle is not phlogiston but heat; nevertheless, it seems highly probable, that these elastic fluids do really consist of the acid united to phlogiston, and expanded by heat. This is also the case with the caustic volatile alkali, now called alkaline air.

In the hepatic air, it has been shown by Mr Bergman, that sulphur exists which contains phlogiston; and there is little reason to doubt that the expansive power here is the same as in other cases. See HEPATIC AIR.

The heat generated during the solution of metals is by Mr Bergman supposed to be owing to the matter

Let a piece of silver, for instance, be put into a dilute nitrous acid, and the surface of the metal will instantly be covered with innumerable bubbles, which arising to the top of the liquor, there burst; and if collected, are found to be nitrous air. The nitrous acid saturates itself with phlogiston more completely than the vitriolic; therefore the elastic fluid produced, or nitrous air, does not unite with water, and scarce retains any vestige of an acid nature. The vitriolic acid, however, differs from the nitrous in this respect, that the phlogiston is absorbed by the latter even beyond the point necessary to obliterate its acid nature. In proof of this, our author adduces the decomposition of hepatic by means of nitrous air.

The marine acid exhibits different phenomena. It naturally contains phlogiston, and therefore can by its means be resolved into a kind of air somewhat similar to that produced by the vitriolic acid when artificially united to the same principle, and which has the same property, viz. that of remaining permanently elastic as long as it is kept from the contact of water. But as the acid we speak of naturally contains phlogiston, there is no necessity of adding more to produce this effect. In the mean time, the marine as well as nitrous air, when in its expanded state, attracts phlogiston, and that with wonderful avidity.

When the marine acid is dephlogisticated, it yields another elastic fluid of a reddish brown colour, having an odour like that of warm aqua regia. This does not unite with water, or only in very small quantity; and by the addition of a proper proportion of phlogiston may be reduced again to common marine acid. It is said that the marine acid may be dephlogisticated by lead as well as by manganese, the nitrous acid, and arsenic.

The fluor acid abounds with phlogiston, and therefore may, without any adventitious matter, be reduced to an elastic fluid. This air is easily distinguished from all others by its corrosion of glass whilst hot.

Vinegar also contains phlogiston; and for that reason, when well dephlegmated, may be reduced without addition into a permanently elastic fluid, called acetous air.

All these fluids seem to be nothing else, according to Mr Bergman, than the acids themselves expanded by phlogiston. "Perhaps (says he) the matter of heat also enters their composition." The experiments lately made on these subjects, however, have put it beyond all doubt, that the expansive principle is not phlogiston but heat; nevertheless, it seems highly probable, that these elastic fluids do really consist of the acid united to phlogiston, and expanded by heat. This is also the case with the caustic volatile alkali, now called alkaline air.

In the hepatic air, it has been shown by Mr Bergman, that sulphur exists which contains phlogiston; and there is little reason to doubt that the expansive power here is the same as in other cases. See HEPATIC AIR.

The heat generated during the solution of metals is by Mr Bergman supposed to be owing to the matter

of heat which had been fixed in the metals; but it may with much more reason be supposed to proceed from the acid. Dr Black has demonstrated, that heat is universally the principle of fluidity; and all fluids, whether acid or not, are found to contain a great quantity of it. It is not probable that solids, even the most inflammable, contain an equal quantity; for it is always observed, that bodies in becoming fluid absorb heat, and throw it out again on becoming solid. Acids in all probability contain a much greater quantity than what is necessary to their fluidity; for we see that the nitrous acid, when poured upon snow, parts with as much heat as is necessary to dissolve the snow, at the same time that it still retains its fluidity. The case is not so with common salt, which is a solid: for though, in a mixture of salt and snow, the latter absorbs as much heat from the salt as is necessary for its own liquefaction; yet the salt could not be held in solution by a liquid of this temperature, were it not that an additional quantity is perpetually absorbed from the adjacent bodies, particularly the atmosphere. But were it possible to prevent this adventitious increase of heat, there is not the least reason to believe that the salt would be dissolved; for the strongest brine, when reduced to the temperature of 0 of Fahrenheit, is decomposed, the salt falling to the bottom in powder, and the water being converted into ice. Add to this also, that the cold produced by spirit of nitre and snow is much more intense than that produced by common salt and snow; which undoubtedly shows, that a solid does not readily part with as much heat as a fluid, and consequently cannot be supposed to contain as much. The solution of metals in acids also demonstrates, that the solid substance has not parted with heat, but absorbed it; for as soon as the solution becomes solid again, *i. e.* when it crystallizes, the temperature becomes higher than before.

213

Why little
or no ela-
stic fluid is
obtained
from me-
tallic cal-
ces.

The calces of metals have not that quantity of phlogiston that is necessary for their metallic state, but yet are not entirely destitute of it; therefore, in their solution, scarce any elastic fluid is generated, unless the fire be continued after exsiccation. Such as contain aerial acid, discharge it immediately in the same form as they had received it. It is remarkable, that Dr Priestley mentions a calx of lead, which, with the acid of phosphorus, produced an inflammable air. By means of the nitrous acid and evaporation to dryness, a pure air is produced. Sometimes a small portion of vitriolic acid air is obtained by means of a proper degree of fire from vitriolic acid, but a far greater quantity of pure air.

214

Metallic
solutions
contain a
calx of the
metal with
various de-
grees of
phlogiston.

The solutions made by the menstrea above mentioned, contain a metallic calx intimately united with the acid, the quantity of phlogiston left being various according to the difference of the menstrea and of the temperature; but the performance of the operation either with or without intense heat, frequently occasions a remarkable difference. That metals are less calcined by the marine than by the nitrous acid, appears from pouring concentrated nitrous acid on tin or antimony; but the difference, if it actually does take place, is less visible in other metals.

Some modern chemists have denied this calcination of metals by solution. They have insisted, that the perfect metals ought to be excepted, as they do not

yield to the most intense fire. On this subject, however, it may be observed, 1. That during their solution nitrous air is always generated, and that of a very perfect kind, which cannot happen without phlogiston; but in this case there is nothing present which can yield phlogiston except the metals. Therefore, 2. The metals, when precipitated from their menstrea by fixed alkalis, both with respect to their external appearance and internal properties, appear to be calcined. Thus the precipitate of gold refuses to unite with mercury, and may be dissolved by marine acid and other simple menstrea, and that without the production of any elastic fluid. 3. Glass may be stained by these calces; but no metal in its perfect state can be taken up by glass.

The common objection is, that the calces of the perfect metals may be reduced by heat alone without the addition of charcoal. Many theories have been invented to solve this phenomenon. Some have supposed, that the matter of heat and light are the same with the phlogiston, and that thus the calces are reduced in the same manner as by charcoal or other substances usually termed *phlogistic*. But in this case we ought to find the calces of the imperfect metals also reduced by a long continuance of heat, as well as the more perfect; which, however, has never yet been known to take place. Some, among whose number is Dr Lewis, have imagined, that the porosity of the vessels, particularly those made of earthen ware, may be such as to admit the passage of phlogistic vapours through them; and he instances the revival of globules of lead in the middle of pieces of glass upwards of an inch in thickness, and that where there was not the least appearance of a crack. But from an experiment of Mr Kirwan's, to be afterwards related, it is much more probable that the reduction is effected by means of the phlogiston contained in one part of the calx attracted by another; by which means the latter is reduced to a perfect metal, while the former becomes somewhat more dephlogisticated. In consequence of this it appears, that the calx of the perfect metals is never totally reduced: for if the operation be performed in a glass retort, the bottom of it is always stained; which indicates the existence of a calx, in however little quantity.

The following fact, Mr Bergman says, has been proposed to him as an inextricable dilemma. "Silver cannot amalgamate with mercury except when in its metallic state, yet both salited and nitrated silver are taken up by mercury; it is therefore not calcined by the acids, but adheres to them in its metallic form." Bergman. This, however, may be easily solved in the following manner. It is well known that the calx of copper, dissolved in the vitriolic acid, is precipitated in its metallic form on the addition of iron, and that by means of a double elective attraction; for the iron, dissolving in the acid, would form an inflammable air by its phlogiston, were not the copper present which takes it up, and thereby becomes insoluble as long as it retains it; but mercury has a stronger attraction for acids than silver: if therefore salited or nitrated silver be triturated with mercury, the silver must be precipitated in a metallic state, and the mercury be calcined by being dissolved. This also takes place, provided there be moisture sufficient to suffer the elective attractions

tions to operate. The superabundant mercury greedily takes up the comminuted silver precipitate; and the *arbores Digne* are nothing more than such an amalgam crystallized. But although the acids cannot take up any metal while it retains its full proportion of phlogiston, various metallic salts are able to effect that solution. Thus nitrated or salited mercury, boiled in water together with the crude metal, can take up a certain portion of it without dephlogistication; and the latter of these salts, even in the *via sicca*, becomes a *mercurius dulcis*, which contains at the same time a crude and a calcined mercury.

218
Phlogiston
the cause
of colour
in metal-
lic solu-
tions.

Perfect solutions should in general be transparent; but some, as has been already mentioned, are distinguished by a peculiar colour. That phlogiston is the chief cause of colour appears from hence, that the black calx of manganese tinges vitriolic acid of a red colour; but on the addition of sugar the tinge is entirely destroyed. Nitrous acid is rendered blue by copper; but when the metal is added in considerable quantity, it becomes of a very deep green. The marine acid, which dephlogisticates the copper less, is yet made green; but by dephlegmation may be so condensed as to become brown. Mr Bergman has sometimes seen a solution of silver green, without the presence of the smallest particle of copper. This depends on the absorption of nitrous air: for let smoking nitrous acid be diluted, on the addition of a certain quantity of water it will be of a deep green; by a greater, blue; and upon a still greater, becomes limpid. By means of the water, the nitrous air is extended to a greater space; and this attenuation gradually increased varies the colours. Hence we see why nitrous acid is made green by a large quantity of copper.

219
Attraction
of phlo-
giston the
cause of
causticity.

Metals dephlogisticated by acid solvents powerfully attract phlogiston; nay, nitrated silver and mercury, and salited antimony, corrode animal substances, in order, as our author supposes, to extract it. "This metallic causticity (says he), which is only to be moderated by phlogiston, ought to be carefully distinguished from the acid causticity, which is repressed by alkalies, and the alkaline, which is mitigated by acids. Colours vary according to the quantity of phlogiston present; and some experiments show, that by a sufficient quantity all colour is entirely destroyed.

320
Phenome-
na attend-
ing the
precipita-
tion of me-
tals by al-
kaline salts.

All metals may be precipitated by alkaline salts; which, by their superior power of attraction, separate them from their menstrua; but their difference with regard to their nature and preparation alters the nature of the precipitate. With the caustic fixed alkali the calces fall almost entirely pure, but loaded with water. The weight is found to be increased by the water, and perhaps (says Mr Bergman) by the matter of heat; but yet less than by the aerial acid. With the aerated fixed alkali, by means of a double decomposition, the aerial acid unites to most calces. The volatile alkali, which naturally contains phlogiston, sometimes phlogisticates the precipitate. It throws down a black or white precipitate of mercury; nay, it makes the orange-coloured precipitate white. Gold receives its fulminating quantity from this precipitant, as is afterwards to be explained. The alkali, which is commonly called *phlogisticated*, generally precipitates metals with an increase of weight.

The acids frequently occasion precipitates, and that for various reasons. By means of elective attraction, mercury, silver, and lead, are taken from the nitrous acid by the addition of the marine or vitriolic. These acids form with the metals new compounds which are difficult of solution in water; they are therefore precipitated in greater or lesser quantity according to circumstances. The nitrous acid is capable of decomposing salited tin and antimony by dephlogisticating the calx of the metals too much; for when these are too much calcined, they cannot be dissolved in any menstruum, as has been already observed.

Metallic solutions are sometimes disturbed by the neutral salts formed by an union of alkalies with acids. Those which contain the vitriolic or marine acids decompose solutions of silver, mercury, or lead, in nitrous acid, and precipitate the metals. By forming a triple combination, the vegetable as well as the volatile alkali, though saturated with vitriolic, nitrous, or marine acid, precipitate platina from aqua-regia; but when the basis is mineral alkali, the salt has no power of this kind. Some metallic salts can decompose others, and precipitate their bases; which may happen whether the acid be different in the two salts or not. Solution of gold affords an example of each of these cases. This is precipitated by martial vitriol; the reason of which will appear from considering the nature of the precipitate: for this, when well washed and dried, not only shows many shining gold-coloured particles, but also unites with mercury by trituration, dissolves in aqua-regia, but not in marine acid alone, together with other circumstances which evince a complete resuscitation of the gold. Martial vitriol, in its ordinary state, contains phlogiston, but very loosely adhering; so that the calx of gold may easily take it from the solution to supply the loss it had sustained during the solution. That this is the true foundation of the process, appears also from the following circumstances, that the weight of the gold is exactly recovered, and that dephlogisticated vitriol will not precipitate this metal. The reason that the surrounding aqua-regia leaves this precipitate untouched is, that the menstruum is diluted and weakened by a large quantity of water; for upon boiling it gently, so as to expel part of the water, the menstruum recovers its solvent power, and takes up the precipitate again.

It is somewhat more difficult to explain the reason why the solution of gold in aqua-regia should be precipitated by a solution of tin in the same menstruum. Here Mr Bergman first supposed that the tin had attracted a superabundance of acid, and taken it from the gold; which being therefore destitute of its proper quantity, must fall to the bottom: but on employing a solution containing a superabundant aqua regia, the same precipitation took place. The cause is therefore not in the menstruum. On examining the precipitate itself, we find nothing like the metallic splendor of gold, but that it entirely resembles a calx. It is easily found by its weight, indeed, that it cannot consist entirely of gold; and in fact chemical examination shows that it consists partly of tin. It cannot be dissolved by the marine acid alone, but is easily taken up by the addition of a little nitrous acid. It scarcely unites with mercury by trituration. These properties seem to indicate, that the gold has so far received phlo-

giston as to resist the marine acid until it receive the assistance of the nitrous; but its earthly appearance, and difficulty of uniting with mercury, evince that it is not in its complete metallic form. The following therefore, according to our author, seems to be the most easy and rational explanation. The solution of tin necessary for this operation must retain as much phlogiston as it possibly can, in a consistence with solubility. This is dropped into a solution of gold very much diluted; by which means the phlogiston remaining in the tin is more loosened, and of consequence more easily attracted by the gold calx, which is thereby brought to a state approximating to completion, so that it can no longer be retained by the menstruum; and the same happens to the tin, by means of the dephlogistication; they must both therefore fall to the bottom mixed intimately with one another. It is probable, says he, that in this case it is the tin which prevents the matter from uniting with mercury.

229
Precipitation of metals by one another, owing to a double elective attraction.

The metals precipitate one another after a certain order, which is the same in all acid menstrea. This precipitation is occasioned by a double elective attraction; for the metal to be precipitated exists in the solution in a calcined state; but being reduced by the phlogiston of the precipitant falls to the bottom, while at the same time the precipitant becomes soluble by calcination: but if the precipitant has been calcined so that a part of it being insoluble is mixed with the precipitate, the metallic splendor is wanting, and it puts on an earthy appearance. A pure precipitate is of the same weight with the metal before solution. The mixed precipitates are less frequently met with, yet gold precipitated by tin exhibits one of that kind.

230
Variations in the order in which the metals precipitate one another.

Though the order in which the metals precipitate one another is constant and never inverted, yet there are many anomalous circumstances which occur in the matter. Thus zinc constantly prevails over iron; iron over lead; lead over tin; tin over copper; copper over silver; silver over mercury, &c. yet it sometimes happens, that a metal which, according to the general rule, precipitates another in its metallic state from one menstruum, precipitates it from another in form of a calx, and not at all from a third. Thus zinc precipitates iron from marine acid in its metallic state, but from the nitrous only in form of a calx. Tin is precipitated by lead from the marine acid in its metallic state, but is not thrown down from the nitrous acid; and from the acetous is precipitated even by iron and zinc in form of a calx; solution of lead in vinegar is not precipitated by iron.

231
Mineral alkali why preferred as a precipitant by Mr Bergman.

In Mr Bergman's experiments on this subject he employed the mineral alkali, as the degree of its saturation with fixed air was more constant. When he had occasion for a caustic alkali, he prepared it by a small quantity of burned lime kept in a close bottle; and the goodness of it was proved by its occasioning no precipitation in lime water. Phlogisticated alkali, or that by which Prussian blue is prepared, was also made use of. With these he made the following observations. Gold dissolved in aqua regia is precipitated by caustic alkali almost black; by the aerated, yellow, as well as by the phlogisticated, unless some iron be present, which frequently happens; but the whole of the gold is scarce ever precipitated, so that the weight cannot be ascertained.

232
How he prepared his caustic alkali.

233
Various precipitates of gold.

Neither the caustic nor aerated mineral alkali precipitate one half of platina dissolved in aqua regia; the precipitate is of an orange colour, which on drying becomes brown. An over-proportion of alkali redissolves the precipitate, and the liquor becomes more dark; nay, the precipitation is so imperfect, that the matter seems to be dissolved even by neutral salts. The phlogisticated alkali does not precipitate the depurated solution, nor even make it turbid, but heightens the colour in the same manner as an excess of alkali.

Solution
and Preci-
pitation.

234
Mineral alkalis precipitate platina imperfectly.

Solution of silver in nitrous acid lets fall a white precipitate by the aerated alkali; brown by the caustic, and of an obscure yellow. By the nitrous and marine acids it lets fall a white precipitate, which with the former consists of more distinct particles, which grow black more slowly with the light of the sun.

235
Precipitates of silver.

Salited mercury lets fall a red precipitate, or rather one of a ferruginous colour, by aerated alkali; but of a more yellowish or orange colour by the caustic. Nitrated mercury prepared without heat, yields a ferruginous precipitate with mineral alkali; a black with caustic: and when prepared with heat, it yields to caustic alkali an orange or reddish yellow precipitate. By phlogisticated alkali it is precipitated from all acids of a white colour; but turns of a brownish yellow when dry. Salited mercury is very sparingly precipitated by this alkali. The precipitate by phlogisticated alkali is again dissolved, if too much of the precipitant be made use of.—Corrosive sublimate must be very cautiously precipitated by caustic, as well as aerated fixed alkali; for the part separated may again be dissolved by a large quantity of water. When too much alkali is used, a new compound arises of a peculiar nature.

236
Of mercury.

Solution of lead in spirit of nitre is precipitated down white by aerated, caustic, or phlogisticated alkali. By using too much alkali, the precipitate by the phlogisticated kind is dissolved with a brownish yellow colour. Vitriol of lead and solution of lead in marine acid are precipitated white.

237
Precipitates of lead;

Blue solution of copper in spirit of nitre is precipitated of a bright green by aerated fixed alkali; by the caustic of a greyish brown, which grows reddish by age. By phlogisticated alkali copper is precipitated of a greenish colour, which grows afterwards of a brownish red, and upon exsiccation almost black. The aerial acid takes up a small quantity of copper during the precipitation, which is again deposited by the heat of boiling.

238
Of copper;

Aerated fixed alkali precipitates iron of a green colour from vitriolic and marine acid; but the precipitate becomes of a brownish yellow, especially on exsiccation; with the caustic alkali it approaches more to black. In the precipitation some part is held in solution by the aerial acid, when the mild alkali is used. With phlogisticated alkali a Prussian blue is formed.

239
Of iron;

Tin is precipitated of a white colour by every alkaline salt, even by the phlogisticated kind; but at length some blue particles appear in the mixture: so that the whole, when collected and dried, appears of a light blue colour. That these blue particles are occasioned by iron appears by calcination; for they become ferrous.

240
Of tin;

Solution and Precipitation. ferruginous, and obey the magnet. Our author has always found a proportion of iron in tin.

241 Precipitates of bismuth; Bismuth is thrown down of a fine white by water and alkalies, particularly the former; phlogisticated alkali throws down a yellow powder, which being mixed with blue particles occasioned by iron, at length appears green. This yellow sediment easily dissolves in nitrous acid.

242 Of nickel; Nickel is precipitated of a whitish green by fixed alkalies; by the phlogisticated alkali of a yellow; and by exsiccation it is condensed into a dark brown mass.

243 Of arsenic; Arsenic dissolved in acids, which prevent too great dephlogistication, may, to a certain degree, be precipitated white by the fixed alkali, even when phlogisticated, but the sediment is found soluble in water; yet nitrous acid, either alone, or joined with the marine, generally dephlogisticates the arsenical acid, which thereby becomes unfit for separation. Arsenic dissolved in marine acid, with the assistance of a little nitrous acid, deposited a white sediment on the addition of a large quantity of phlogisticated alkali. The sediment was mixed with Prussian blue. This was dissolved in water, and freed by frequent filtration from the blue particles; and at length, on evaporating to dryness, yielded a semipellucid mass.

244 Of cobalt; Cobalt dissolved in acids is thrown down by fixed alkali, whether aerated or caustic, of a reddish blue, which grows darker on exsiccation, especially when the former alkali has been used. Phlogisticated alkali throws down a powder of almost the same colour, which, upon exsiccation, becomes of a reddish brown.

245 Of zinc; Zinc is precipitated white by aerated and caustic fixed alkalies, as also by the phlogisticated alkali; but this last becomes of a citron colour on exsiccation: a small portion of aerial acid may easily escape during the precipitation.

246 Of antimony; Antimony is precipitated white by alkalies. When the phlogisticated alkali is used, some blue particles are almost always precipitated at the same time, though the regulus had been prepared without any iron. This operation should be cautiously conducted, lest some part be taken up by the alkaline salt.

247 Of manganese. Manganese procured by reduction from common magnesia nigra, generally renders menstrua brown, and with aerated alkali yields a yellowish brown sediment; with the caustic, one still darker; with the phlogisticated, first a blue, then a white, powder is separated, the mixture of which renders the mass a black green. To obtain a pure and white calx of manganese, we must dissolve in pure vinegar the precipitate thrown down by caustic alkali; for there still remains a quantity of iron which is taken up by the aerial acid. This acetous solution contains little or nothing of iron. That metal may also at first be separated by a small quantity of volatile alkali.

The common solution of the regulus is not perfectly precipitated by the aerated alkali; and upon evaporating the remaining liquor spontaneously to dryness, grains of a metallic splendour, and not unlike copper, are deposited on the glass. The nitrous acid attracts these readily, though they are only partially

dissolved by it; but on the addition of zinc, nothing falls besides the manganese, though at first it is a little reddish. With phlogisticated alkali, we obtain a yellow precipitate like pure manganese, provided the solution has deposited the iron when too much dephlogisticated by age. But the new solution yields a precipitate almost like that which is obtained from common regulus. The yellow sediment may be dissolved in water.

The following is Mr Bergman's table of the quantities of precipitate of different metals, thrown down from various menstrua by the different alkalies. "On comparing the weights (says he), a question occurs concerning the cause of such enormous differences; and it is plain, that this cause must be sought for in the precipitates themselves.—The fixed alkali saturated with aerial acid, when added to the solution, is taken up by the more powerful menstruum; and the weaker is of course expelled, and is absorbed by the calx as it falls, in greater or lesser quantity according to circumstances. That this is actually the case is easily demonstrated:—Let a bottle containing a quantity of nitrous acid be accurately weighed. Let there be put into it, for instance, 132 parts of lead precipitated by aerated alkali; and not only an effervescence will be observed, which continues until the very last particle is dissolved, but when the solution is finished, a deficiency of weight is discovered, which amounts nearly to 21, and which is undoubtedly owing to the extrication of aerial acid. But $132 - 21 = 111$; a weight which still considerably exceeds that of the metal. Upon distillation nearly eight of water are discovered. There yet remain therefore three, which by violent heat are increased by seven; for 132 of the calx well calcined, yield 110. The whole increment of weight then does not depend on the water and aerial acid. The same thing is evinced by considering the precipitate of lead by the caustic alkali; in which case there can be no aerial acid, nor does any effervescence accompany the solution. If we suppose the quantity of water equal in both cases, yet even on this supposition the whole excess of weight is not accounted for; for $116 - 8 = 108$. It is therefore probable, that the matter of heat is attached to the calx (A).—In proof of this opinion, and that caustic alkalies contain the matter of heat, our author adduces several arguments, of which the following is the strongest.—"Let the heat occasioned by the mixture of any acid and caustic alkali be determined by a thermometer; let then an equal portion of the same menstruum be saturated with a metal; afterwards, on the addition of an equal quantity of caustic alkali, it will be found, either that no heat is generated, or a degree very much less than before.—Some of the matter of heat therefore is taken up and fixed, which also generally makes the colours of the precipitates more obscure; and in distillation with sal-ammoniac, communicates to the volatile alkali the quantity that had been taken away."

In this instance also, however, our author seems to have been deceived. It has already been observed, that in all solutions generating heat, it most probably comes from the fluid. Acids contain a quantity sufficient

Solution and Precipitation.

248 On the cause of such great variations in the weight of precipitates.

249 Argument in favour of the weight of precipitates being augmented by the matter of heat.

250 Insufficient.

(A) This increase of weight is with more probability to be ascribed to a remainder of the acid.

Solution
and Preci-
pitation.

ficient not only for their own fluidity, but for rendering solid bodies fluid also. After they have dissolved the metal, however, this superfluous quantity is employed; and when the caustic alkali is added, if in a solid form, it is again employed in giving fluidity to the alkali; or if the alkali be already dissolved, the increased quantity of fluid makes the heat extricated less perceptible.

“What has been said of lead (continues our author), is also true of the other metals, a few excepted, which seem to take up little or no aerial acid; such are tin, antimony, gold and platina.—But some precipitates retain also a quantity of the menstruum.

251
A quantity
of the men-
struum re-
tained by
some pre-
cipitates.

Thus, corrosive mercury, precipitated by aerated alkali, retains a portion of marine acid, which cannot be washed off by water; but, by caustic alkali, the precipitate may be obtained, either free of the acid altogether, or in a great measure. In this case, as in many others, the aerial acid seems to generate a triple salt, scarce at all soluble. The presence of the marine acid is easily discovered by solution of silver in nitrous acid, if the menstruum has been pure. Hence we observe another difference in mercury precipitated from marine acid, according as we employ the aerated or caustic alkali; the latter, well washed, and put into volatile alkali, is scarcely changed in colour; but the former instantly grows white, generating a species of sal-alembroth, but containing so little marine acid as not to be easily soluble in water. The calces which retain any of their former menstruum, generally give over on distillation a small portion of sublimate. The mercurial calx just mentioned, exposed to a sufficient degree of heat, is partly reduced to crude mercury, partly to mercurius dulcis, by means of its remaining marine acid. This mercurius dulcis did not exist in the precipitate; for in that case it would be easily discovered by acids in which it is not soluble, and would grow black with caustic alkali, neither of which take place, so that it must be generated during the distillation.”

cury.

253
Advanta-
ges to be
derived
from the
examina-
tion of me-
tallic pre-
cipitates.

Mr Bergman concludes his dissertation, with an enumeration of the advantages resulting from the careful examination of metallic precipitates.—These are, 1. That thus the theory of the operation will be more perfectly understood. 2. We may discover the more useful and remarkable properties. 3. A foundation is thereby laid for essaying in the moist way, from the bare knowledge of the weights. “It may be objected (says he), that the doctrine of the weights is very fallacious; that they vary in different precipitates; that by imperfect precipitation something remains in the liquor; and that sometimes extraneous matters remain in them. All this is true; but if the mode of operation be the same, the results of the experiments will be equally constant. Thus, let us suppose that a certain quantity of metal *a*, precipitated in a certain manner, makes a weight *b*; if that same manner be exactly employed, we may fairly conclude, that a quantity of precipitate *nb*, occurring in any case, is correspondent to a quantity of perfect metal *na*; though, in the fundamental experiment, the precipitation is either incomplete, or some extraneous matter may be present. 4. The nature of metals is thus illustrated. Platina, nickel, cobalt, and manganese, are supposed by some to derive their origin from a mixture of other metals. But if iron necessarily enters into the composition of platina,

when the latter is dissolved in aqua regia, it ought to yield a Prussian blue on the addition of phlogisticated alkali; which indeed is the case when common platina is employed, but not with that which is well depurated.

In like manner, if iron, adhering very obstinately to nickel, formed a great part of the latter, the precipitates obtained from it by alkalies could not differ from martial precipitates so much as they do in colour, weight, and other properties. The same holds true of cobalt and manganese. The regulus obtained from the latter contains about 0.08 of iron, which affects the mixture in the following manner. An hundred pounds dissolved in an acid menstruum, yields, by treatment with phlogisticated alkali, a powder consisting partly of blue, partly of brownish yellow particles, equal in weight to 150 pounds; but eight pounds of iron yield 48 of Prussian blue, nearly $\frac{1}{3}$ of the whole mass of precipitate: whence it follows, that 100 parts of pure manganese yield to phlogisticated alkali scarcely 111; i. e. nearly six times less than an equal weight of iron.

“Lastly, by this method of examining precipitates, it may perhaps be possible to determine the unequal quantities of phlogiston in different metals; for a given weight of precipitating metal does not yield an equal quantity of precipitate: thus, for instance, copper is able to precipitate from nitrous acid four times its weight of silver.”

Kirwan's
definition
of chemi-
cal attrac-
tion.

Mr Kirwan has made a great number of experiments on the attractive powers of the mineral acids to various substances, and greatly illustrated the operations both of solution and precipitation. Chemical attraction, he observes, "is that power by which the invisible particles of different bodies intermix and unite with each other so intimately, as to be inseparable by mere mechanical means." Thus it differs from the attraction of cohesion, as well as from that of magnetism and electricity, as not acting with the indifference observed to take place in these powers, but causing a body already united to another to quit that and unite with a third; whence it is called *elective* attraction. Hence attraction of cohesion often takes place betwixt bodies that have no chemical attraction for each other; as for instance, bismuth and regulus of cobalt, which cannot be made to unite together by fusion, though they cohere with each other so strongly, that they cannot be separated but by the blow of a hammer.

for its dif-
ferent ba-
ses.

To determine the degrees of attraction betwixt different substances, M. Geoffroy laid it down as a general rule, that when two substances are united, and either quits the other to unite with a third, that which thus unites to the third must be said to have a greater affinity to it than to the substance it has quitted. In many cases, however, the seemingly single decomposition is in truth a double one. Thus, when the vitriolic acid expels the air from a fixed alkali, it does not necessarily follow, that the acid is more attracted by the alkali than the fixed air; for here though the latter resigns its place to the acid, yet the acid gives out its fire to the air; whence a decomposition might take place, even though the attractive powers of both the vitriolic and aerial acid to the alkali were equal.

To attain to any certainty in this matter, therefore, it is necessary to determine the quantity and force of each of the attractive powers, and denote it by numbers. The necessity of this has been observed by Mr Morveau and Mr Wenzel, who have both proposed methods for answering the purpose; but Mr Kirwan has showed that both are defective: and he tells us, that the discovery of the quantity of real acid in each of the mineral acid liquors, with the proportion of real acid taken up by a given quantity of each basis at the point of saturation, led him unexpectedly to what seems the true method of investigating the quantity of attraction which each acid bears to the several bases to which it is capable of uniting: "for it was impossible

(says he) not to perceive, 1. That the quantity of real acid necessary to saturate a given weight of each basis is inversely as the affinity of each basis to such acid. 2. That the quantity of each basis requisite to saturate a given quantity of each acid is directly as the affinity of such acid to each basis. Thus 100 grains of each of the acids require for their saturation a greater quantity of fixed alkali than of calcareous earths, more of this earth than of volatile alkali, more of this alkali than of magnesia, and more of magnesia than of earth of alum.

"If an acid be united to less of any basis than is requisite for its saturation, its affinity to the deficient part of its basis is as the ratio which that deficient part bears to the whole of what the acid can saturate. Thus, if 100 grains of vitriolic acid, which can saturate 110 of calcareous earth, be united only to 55, its affinity to the deficient 55 parts should be estimated one half of its whole affinity; but its affinity to the retained part is as its whole affinity."

To explain the decompositions in which these acids are concerned, we must consider, first, the powers which resist any decomposition, and tend to keep the bodies in their present state; and, secondly, the powers which tend to effect a decomposition and new union; the former our author calls *quiescent affinities*, the latter *divellent*. A decomposition will therefore always take place when the sum of the divellent affinities is greater than the quiescent; and, on the contrary, no decomposition will happen when the sum of the quiescent affinities is greater than that of the divellent. All we have to do therefore is to compare the sums of each of these powers. The method our author takes to compare the affinities together is by the following table; in which the quantity of alkali, earth, &c. saturated by 100 grains of each of the mineral acids, is stated.

	Veg. fixed alkali.	Mineral alkali.	Calcar. earth.	Vol. alk.	Mag- nesia	Earth of alum.	Quantity of acid ra- ken up by various ba- ses.
Vitriolic acid	215	165	110	90	80	75	268
Nitrous acid	215	165	96	87	75	65	
Marine acid	215	158	89	79	71	55	

These numbers he considers as adequate expressions of the quantity of each of the affinities. Thus the affinity of the vitriolic acid to fixed vegetable alkali is to the affinity with which it adheres to calcareous earth as 215 to 110; and to that which the nitrous acid bears to calcareous earth as 215 to 96, &c. Hence we sum up the powers of affinity betwixt any number of different substances, and account for their decompositions, as in the following example of the double decomposition, which takes place when a solution of vitriolated tartar and solution of lime or chalk in nitrous acid are mixed together.

<i>Quiescent Affinities.</i>		<i>Divellent Affinities.</i>	
Vitriolic acid to vege- table fixed alkali,	215	Vitriolic acid to calca- reous earth,	110
Nitrous acid to calca- reous earth,	96	Nitrous acid to vege- table alkali,	215
Sum of quiescent affinities	311	Sum of divellent affinities	325

Hence we see that a double decomposition must ensue. The same will be produced, if instead of vitriolated tartar we make use of Glauber's salt; for the sum of the

pitation.

the quiescent affinities is 261, of the divellent 275; with vitriolic ammoniac the sum of the quiescent is 186, of the divellent 195, &c. In mixing vitriolated tartar with solution of magnesia in nitrous or marine acids, a double decomposition takes place though invisibly, as the vitriolic Epsom salt is very soluble in water, and therefore cannot be precipitated like selenite. In the former case the sum of the quiescent powers is 290, of the divellent 295; in the second 286 and 295.

271
Coinci-
dence of
the above
table with
experience.

Other decompositions take place in the same manner; and from all the facts which our author had occasion to observe, he concludes, that the quantity of each affinity, as determined in the above table, coincides exactly with experience; and that these decompositions are perfectly consistent with the superior affinity which has been hitherto observed in the vitriolic and nitrous acids with fixed alkalies over the calcareous earths; nor do they infringe in the least the known laws of affinity, as has been insinuated by some chemists. One fact only, mentioned in Dr Crell's Journal, seems to be repugnant to what is here advanced; and that is, that if solutions of one part of alum and two of common salt be mixed together, evaporated, and set to crystallize, a Glauber's salt will be formed; though, in this case, the sum of the quiescent affinities is 233, and that of the divellent only 223. Mr Kirwan repeated this experiment without success; and Dr Crell himself owns that it will not succeed but in the most intense cold. If it does succeed at all, he says the decomposition must arise from a large excess of acid in the alum, which acted upon and decomposed the common salt: and this explanation is confirmed by the small proportion of Glauber's salt said to be obtained by this process; for from 30 lb. of common salt and 16 of alum, only 15 lb. of Glauber's salt were produced; whereas, if the whole of the alum had been decomposed, there should have been formed, according to Mr Kirwan's computation of the quantity of acid in the different salts, 29½ lb, or, according to Mr Bergman's, 22 lb. of Glauber's salt.

273
Formation
of triple
and qua-
druple salts.

In some cases, the neutral salts have a power of uniting, without any decomposition, or with only a very small one, to a third substance; thus forming triple salts, and sometimes quadruple; which often causes anomalies that have not yet been sufficiently investigated. Volatile alkalies in particular are possessed of the power of uniting with neutral salts in this manner. Hence they seem to precipitate magnesia from Epsom salt, even when perfectly caustic; but this is owing to their combination with that salt, and forming a triple one, which is insoluble in water.

274
Volatile al-
kalies par-
ticularly
form salts
of this
kind.

It seems extraordinary that, according to Mr Kirwan's table, the three mineral acids should have the same affinity to vegetable fixed alkalies, when it is well known that the vitriolic will expel either of the other two from an alkaline basis. In explication of this, Mr Kirwan observes, that nitre is decomposed by the marine acid; and that Glauber's salt and vitriolic ammoniac are decomposed by that of nitre; and that these salts, as well as cubic nitre and nitrous ammoniac, are decomposed by the marine acid.

275
Vitriolic
salts de-
composed

trous and
marine a-
cids.

Mr Kirwan is of opinion, that these decompositions are the effect of a double affinity, or at least of compound forces. He suspected that they arose from the

Nº 71.

different capacities of the acids for elementary fire; and to determine this matter, he made the following experiments, in which the decompositions were not discovered by crystallization, but by tests.

1. Having procured a quantity of each of the three mineral acids containing the same proportion of real acid, and reduced them to the temperature of 68° of Fahrenheit, 100 grains of vitriolic acid, containing 26.6 of real acid, was projected upon 480 grains of oil of tartar at the same temperature, by which the thermometer was raised to 138°.

2. An hundred grains of spirit of nitre, containing also 26.6, projected on 480 grains of oil of tartar, produced only 120° of heat.

3. An hundred grains of spirit of salt, the specific gravity of which was 1220, and which contained the usual proportion of real acid, raised the thermometer from 69 to 129.

"Hence (says he) it follows, that the vitriolic acid contains more specific fire, or at least gives out more by uniting with fixed alkalies, than either the nitrous or marine; and therefore when the vitriolic acid comes in contact with either nitre or salt of Sylvius, its fire passes into these acids, which are thereby rarefied to a great degree, and are thus expelled from their alkaline basis, which is then seized on by the vitriolic."—On this, however, it is obvious to remark, that, according to Mr Kirwan's explanation, the marine acid, as giving out more specific heat, ought to expel the nitrous from an alkaline basis; which, however, is not the case. Something else, therefore, besides the mere quantity of specific heat, must here be taken into consideration. Mr Kirwan, however, goes on to prove the truth of his theory by the following experiments.

4. To 400 grains of vitriolic acid, whose specific gravity was 1.362, sixty grains of nitre were added; on which the thermometer fell from 68° to 60°. During the time of this descent, the nitrous acid was not expelled; for some filings of copper, put into the mixture, were not acted upon in the least; but in five minutes afterwards they visibly effervesced, which showed that the nitrous acid began to be expelled; for the vitriolic acid does not act upon copper but by a boiling heat.

5. Sixty grains of nitre were put to 400 of oil of vitriol, whose specific gravity was 1.870; the thermometer instantly rose from 68° to 105°, and the nitrous acid was expelled in a visible fume.—"These experiments (says Mr Kirwan) prove, 1. That neutral salts are not decomposed by mere solution in an acid different from their own. 2. That the nitrous acid, being converted into vapour, had imbibed a large quantity of fire. But as the vitriolic acid, in both these experiments, was used in much larger quantity than was necessary to saturate the alkali of the nitre, sixty grains of the latter were put into 64 of the above mentioned dilute spirit of vitriol, which contained the same quantity of real vitriolic acid that the 60 grains of nitre did of the nitrous; with the addition of 40 grains of water and a few copper-filings. In less than two hours the copper was acted upon, and consequently the nitrous acid was expelled.

6. To 400 grains of oil of vitriol, of the specific gravity of 1.870, 100 grains of common salt were added. An effervescence immediately ensued,

284 Both the nitrous and marine acids receive fire from the vitriolic during their expulsion.

285 On the decomposition of vitriolated tartar by nitrous acid.

286 Acids unite to alkalis by giving out fire, and quit them by receiving it.

287 Vitriolated tartar cannot be decomposed by diluted nitrous acid.

288 Decomposition of vitriolated tartar by marine acid.

and the marine acid rose in white vapours. A thermometer held in the liquor rose only 4 degrees, but in the froth it ascended to 10°, and fell again upon being replaced in the liquor. Hence Mr Kirwan concludes, that the vitriolic acid gives out its fire to the marine; and that this latter received more than it could absorb even in the state of vapour, and therefore communicated heat to the contiguous liquor. It appears to him also, that the nitrous and marine acids receive fire from the vitriolic, and are thrown into a vaporous state, or at least rarefied to such a degree as to be expelled from their alkaline basis, though their affinity with that basis may be equally strong with the vitriolic.

7. To ascertain the manner in which vitriolated tartar and Glauber's salt are decomposed by spirit of nitre, 60 grains of powdered tartar of vitriol were put into 400 of nitrous acid, whose specific gravity was 1.355, and which contained about 105 grains of real acid. The thermometer was not affected by the mixture; but in 24 hours the vitriolic acid was in part disengaged, as appeared by the acid mixture acting upon regulus of antimony, which neither pure vitriolic nor pure nitrous acid will do by themselves. On putting the same quantity of vitriolated tartar into 400 grains of spirit of nitre whose specific gravity was 1.478, the thermometer rose from 67° to 79°; the vitriolated tartar was quickly dissolved, and the regulus of antimony showed that the vitriolic acid was disengaged. Hence it appeared, that the nitrous acid, having the same affinity with the basis of vitriolated tartar as the vitriolic, but giving out, during the solution, more fire than was necessary to perform the solution, the vitriolic, receiving this fire, was disengaged: for as it cannot unite to alkalis without giving out fire; so when it receives back that fire, it must quit them. The reason why the nitrous acid, which specifically contains less fire than the vitriolic, gives out so much is, that its quantity in both these experiments is far greater than that of the vitriolic; it being in the first as 105 to 17, and in the last as 158 to 17.

8. To 60 grains of spirit of nitre, whose specific gravity was 1.355, Mr Kirwan added 1000 grains of water; and into this dilute acid put 60 grains of vitriolated tartar, containing exactly the same quantity of real acid that the 60 grains of nitrous acid did. In eight days the vitriolated tartar was almost entirely dissolved, and without any sign of its decomposition; and no nitre was found upon evaporating the liquor. Hence he concludes, that the nitrous acid can never decompose vitriolated tartar, without the assistance of heat, but when its quantity is so great that it contains considerably more fire, and by the act of solution is determined to give out this fire. This salt is also decomposed, in similar circumstances, by the marine acid; though still more slowly and with more difficulty than by the nitrous, as appears by the following experiments.

9. Into 400 grains of spirit of salt, whose specific gravity was 1.220, were put 60 grains of vitriolated tartar. The thermometer was not affected in the least, and the salt dissolved very slowly. Some pulverized bismuth was added to try whether the vitriolic acid was disengaged; and in 12 hours part of it was dis-

solved, so that it could not be precipitated by water. This showed, that part of the vitriolic acid was dislodged; for this semi-metal cannot be kept in solution when much diluted with water, excepting by a mixture of marine and vitriolic acids.

In this experiment the quantity of marine acid was much greater than that of the vitriolic; and therefore it was capable of dislodging it. This circumstance alone, however, is not sufficient; the acid must be disposed to give out by solution that quantity of fire which it is necessary the vitriolic should receive in order to its quitting the basis to which it is united; and therefore when Mr Cornette added two ounces of spirit of salt to half an ounce of vitriolated tartar already dissolved in water, no decomposition took place. The reason of this was, that as the vitriolated tartar was already dissolved, no cold nor heat was generated by the mixture; and therefore the spirit of salt could not give out any fire. Glauber's salt is more easily decomposed by marine acid than vitriolated tartar, on account of its being more easily soluble in spirit of salt; and likewise because its alkaline basis takes up an equal quantity of both acids: consequently the marine gives out more fire in uniting to the basis of Glauber's salt than on being united to that of vitriolated tartar. Vitriolic ammoniac is also decomposed by means of marine acid; but in all these cases, the quantity of marine acid must greatly exceed that of the vitriolic contained in the salt to be decomposed; and it must be remarked, that according to the observations of Mr Bergman, the decomposition of Glauber's salt or vitriolic ammoniac by this acid is never complete.

On the same principles the marine acid decomposes salts which have the nitrous acid for their basis. Mr Cornette found, that cubic nitre was more easily decomposed by it than that which has vegetable alkali for its basis. Accordingly, during the solution of prismatic nitre, only three degrees of cold were produced; but six by the solution of cubic nitre; which shows that the spirit of salt gave out more fire in the latter case than in the former; and its quantity must always be greater than that of the nitrous acid contained in the mineral alkaline basis; because this basis requires for its saturation more of the marine than of the nitrous acid. The nitrous acid, however, in its turn decomposes salt of Sylvius and common salt; but it must always be in greater quantity than the marine to produce that effect.

10. Sixty grains of common salt being added to 400 of colourless spirit of nitre, whose specific gravity was 1.478, the mixture quickly effervesced and grew red, yet the thermometer rose but two degrees; which showed that the marine acid had absorbed the greater part of the fire given out by that of nitre; the decomposition was likewise hastened by the superior affinity of the nitrous acid to the alkaline basis of the sea-salt: hence the decomposition of sea-salt by means of nitre takes place without any solution; but spirit of salt will not decompose cubic nitre until it has first dissolved it. This mutual expulsion of the nitrous and marine acids by each other, is the reason why aqua-regia may be made by adding nitre or nitrous ammoniac to spirit of salt, as well as by adding common salt or sal ammoniac to spirit of nitre.

Selenite cannot be decomposed either by nitrous or marine

marine acid; because it cannot be dissolved in either without the assistance of foreign heat. It must likewise be observed, that in all decompositions of this kind, when the liquor has been evaporated to a certain degree, the vitriolic acid expels in its turn the nitrous or marine acid to which it had already yielded its basis. The reason of this is, that the free part of the weaker acids being evaporated, the neutral salts begin to crystallize, and then giving out heat, the vitriolic absorbs it; and thus reacting upon them, expels them from the alkali or earth to which they are united.

Mr Kirwan found much more difficulty in determining the attractive powers of the different acids to the metals than to alkaline salts or earths. Some of the difficulties met with in this case arose from the nature of metallic substances themselves. Their calces when formed by fire always contain a quantity of air, which cannot be extracted from them without great difficulty, and is very soon re-absorbed; and if formed by solution, they as constantly retain a part of their solvent or precipitant; so that the precise weight of the metalline part can scarce be discovered. Our author, therefore, and because metallic calces are generally insoluble in acids, chose to have the metals in their perfect state: and even here they must lose a part of their phlogiston before they can be dissolved in acids, and a considerable part remains in the solution of the acid and calx; which last quantity he endeavoured to determine.

A new difficulty now occurred, arising from the impossibility of finding the real quantity of acid necessary to saturate the metal, for all metallic solutions contain an excess of acid: the reason of which is, that the salts formed by a due proportion of acid and calx are insoluble in water without a further quantity of acid; and in some cases this quantity, and even its proportion to the aqueous part of the liquor, must be very considerable, as in solutions of bismuth. It was

Quantities of the different metals taken up by acid.	100 grains of	Iron.	Copper.	Tin.	Lead.	Silver.	Merc.	Zinc.	Bismuth.	Nickel.	Cobalt.	Reg. of ant.	Reg. of arsen.
Vitriolic acid		270	260	138	412	390	432	318	250 310	320	360	200	260
Nitrous acid		255	255	120	365	375	416	304	290	300	350	194	220
Marine acid		265	265	130	400	420	438	312	250 320	275 310	370	198	290

Though from this table, compared with the former, we might suppose that metals, having a greater attraction for acids than alkalies, could not be precipitated by them, yet Mr Kirwan observes, that the common tables, which postpone metallic substances to alkaline salts, are in reality just, though there can scarce be any room to doubt that almost all metallic substances have a greater affinity with acids than alkalies have. The common tables, he says, are tables of precipitation rather than of affinity, as far as they relate to metallic substances. These precipitations, however, are constantly the result of a double affinity and decomposition; the precipitating metal yielding its phlogiston to the precipitated one, while the precipitated metal yields its acid to the other. Thus, though copper in its metallic form precipitates silver and mercury from the nitrous acid, yet the calx will precipitate neither.

The superior attraction the nitrous acid has to silver

in vain attempted to deprive those solutions of their excess of acid by means of caustic alkalies and lime-water; for when deprived of only part of it, many of the metals were precipitated, and all of them would be so if deprived of the whole. As the solution of silver, however, can be very much saturated, Mr Kirwan began with it, and found that 657 grains of this solution contained 100 grains of silver, and 31.38 grains of real acid, after making the proper allowance for the quantity dissipated in nitrous air. Nine grains of this solution tinged an equal quantity of solution of litmus as red as $\frac{8}{10}$ of a grain of real acid of spirit of nitre would have done; whence our author concluded, that 9 grains of his solution of silver contained an excess of $\frac{8}{10}$ of a grain of real silver: according to which calculation, the whole quantity ought to have contained 5.6 grains; which deducted from 31.38, leaves 25.78 grains for the quantity of acid saturated by 100 grains of silver.

As the vitriolic solutions of tin, bismuth, regulus of antimony, nickel, and regulus of arsenic, contain a large excess of acid, Mr Kirwan saturated part of it with caustic volatile alkali before he tried them with the infusion of litmus; and the same method was used with solutions of iron, lead, tin, and regulus of antimony in the nitrous and marine acids. The proportion of vitriolic and marine acid taken up by lead, silver, and mercury, were determined by computing the quantity of real acid necessary to precipitate these metals from their solutions in the nitrous acid; which seemed to be the most exact method of determining this point. The result of all the experiments was, that 100 grains of each of these acids take up at the point of saturation of each metallic substance, dephlogisticated to such a degree as is necessary for its solution in each acid, the quantities marked in the following table.

rather than fixed alkali, appears from the following experiment. If a solution of silver in nitrous acid be poured into a mixed solution of alkali and sea-salt, the silver will be precipitated by the sea-salt into a luna cornea, and not by the loose alkali contained in the liquor. "Now (says Mr Kirwan), if the nitrous acid had a greater affinity to the free alkali than to the silver, it is evident that the silver would be precipitated pure, and not in the state of luna cornea; but from its being precipitated in this state, it is plain, that the precipitation was not accomplished by a single but by a double affinity. Hence also the marine acid appears to have a greater attraction to silver than the nitrous has to fixed alkalies. The result is similar when we make use of solutions of lead or mercury in the nitrous acid. Mr Bayen has also shown, that vitriol of lead and corrosive sublimate mercury cannot be deprived of more than half their acid, even by caustic fixed alkalies.

With regard to lead, if perfectly dry salt be project-
ed on this metal heated to ignition, the common salt will
be decomposed, and plumbum corneum formed. Nor
can we attribute this to the volatilization of the alkali
by heat; for the alkali is as fixed as the lead, and
must therefore be caused by the superior attraction
which the calx of this metal, even when dephlogisti-
cated, has for the marine acid. Mr Scheele informs
us, that if a solution of common salt be digested with
litharge, the common salt will be decomposed, and a
caustic alkali produced. It may also be decomposed
simply by letting its solution pass slowly through a fun-
nel filled with litharge; and the same thing happens
to a solution of calcareous earth in marine acid; which
shows that the decomposition takes place merely by the
superior degree of attraction betwixt the acid and me-
tallic calx (A).

That acids have a greater attraction for metallic
earths than volatile alkalies, is still more evident. Luna
cornea is soluble in volatile alkalies; but if this solution
be triturated with four times its weight of quicksilver, a
mercurius dulcis, and not sal ammoniac, is formed. The
reason why alkalies and earths precipitate all metallic so-
lutions is, that the metals are held in solution by an ex-
cess of acid. Even if the alkaline and earthy substance
did no more than absorb this excess of acid, a precipi-
tation must necessarily ensue; but they not only take up
this superabundant acid, but also the greater part of
that which is necessary to saturate the metallic earth.
Thus they are enabled to do by means of a double af-
finity; for during the solution of metals, only a small
part of the phlogiston, comparatively speaking, escapes,
the remainder being retained by the compound of acid
and calx. When therefore an alkali or earth is added
to such a solution, the phlogiston quits the acid, and
joins with the calx, while the greater part of the acid
reunites to the precipitate. Notwithstanding this great
affinity, however, of metallic earths to acids, there are
but few instances of their decomposing those salts
which have an alkali or an earth for their basis, by rea-
son of the inability of the acids, while combined with
these bases, and thereby deprived of a great part of
their specific fire, to volatilize the phlogiston combi-
ned with the metallic earths, which must necessarily
be expelled before an acid can combine with them: and
as to the metallic calces, they are generally combined
with fixed air, which must also be partly expelled; but
ammoniacal salts (containing much more fire, for they
absorb it during their formation) for that reason act much
more powerfully on metals. Allowing then the affini-
ties of the mineral acids with metallic substances to be
as above, all double decompositions, in which only salts
containing these acids united to alkaline, terrene, or
metallic bases, are concerned, admit of an easy explana-
tion; nay, says Mr Kirwan, I am bold to say, they
cannot otherwise be explained. Thus, if a solution
of tartar vitriolate, and of silver in the nitrous acid, be
mixed in proper proportion, nitre and vitriol of silver will
be formed; and this latter for the most part precipitated.

Thus also, if, instead of a solution of tartar vitrio-
late, that of Glauber's salt, or of vitriolic sal ammo-
niac, selenite, Epsom salt, or alum, be used, the ba-
lance is constantly in favour of the divellent powers; and
a precipitation is the consequence, though but slight
when selenite or alum are used.

Solution of silver is also precipitated by the vitriolic
solutions of iron, copper, tin, and probably by many
other solutions of metals in the vitriolic acid; for this
reason, among others undoubtedly, that they contain
an excess of acid: but if a saturated solution of silver
be mixed with a very saturated solution of lead or mer-
cury in the vitriolic acid, the silver will not be preci-
pitated; and in both cases the balance is in favour of
the quiescent affinities.

All the marine neutral salts, whether the basis be al-
kaline, terrene, or metallic, decompose the nitrous solu-
tion of silver; and these decompositions are constantly
indicated by the balance of affinities already described.
The same thing also takes place with solution of silver
in the vitriolic acid, as is indicated also by the same
table. The nitrous solution of lead is also decompo-
sed, and the metal for the most part precipitated, un-
less the solution be very dilute in the form of vitriol of
lead, by all the neutral salts containing either the vi-
triolic or marine acid, excepting only the combination
of silver with marine acid, which precipitates it in no
other way than by its excess of acid.

Solution of lead in marine acid is decomposed by all
the neutral salts containing the vitriolic acid, excepting
only selenite and solution of nickel in oil of vitriol. These
can only precipitate it by virtue of an excess of acid.

Nitrous solution of mercury is decomposed by all the
neutral salts containing the vitriolic acid, except vitriol
of lead, which only decomposes it by an excess of acid.

All the salts containing marine acid decompose the
nitrous solution of mercury, excepting the combina-
tions of marine acid with silver and lead, which decom-
pose it by excess of acid.

These salts also decompose vitriol of mercury, tho'
a precipitation does not always appear, owing, as Mr
Kirwan supposes, to the facility with which a small quan-
tity of the marine salt of mercury is soluble in an excess
of acid. Marine salt of silver, however, decomposes vitriol
of mercury only through its excess of acid. Hence we
see why luna cornea can never be reduced by fixed al-
kalies without loss; and were it not that the action of
the alkali is assisted by heat, it never could be reduced
by them at all.

When oil of vitriol is mixed with a solution of cor-
rosive sublimate, a precipitate falls: but this, as Mr
Bergman remarks, does not proceed from a decompo-
sition

3 F 2

(A) These experiments have been repeated by many other chemists without success; and Mr Wieg-
leb informs, that none of those who have attempted to decompose sea-salt by means of lead, ever found their me-
thods answer the purpose.

sition of the mercurial salt, but from an abstraction of the water necessary to keep the sublimate dissolved.

In the foregoing table two different affinities are assigned to the vitriolic acid with regard to bismuth and nickel; one showing the affinity which these acids bear to the metals when dephlogisticated only by solution in the acids; the other that which the acids bear to them when more dephlogisticated, as when they are dissolved in the nitrous acid. On the other hand, all the acids have less affinity with the calces of iron, zinc, tin, and antimony, when they are dephlogisticated to a certain degree; but our author found himself unable to give any certain criteria of this dephlogistication.

The most difficult point to be settled was the precipitation of metals by each other from the mineral acids. To determine this it was necessary to find the quantity of phlogiston in each of them, not only in their natural state, but according to their various degrees of dephlogistication by each of the acids. The substance he chose for determining the absolute quantity of phlogiston in a metallic substance was regulus of arsenic. An hundred grains of this semimetal dissolved in dilute nitrous acid yielded 102.4 cubic inches of nitrous air; which, according to his calculations on that subject, contain 6.86 grains of phlogiston: and hence he concluded that 100 grains of regulus of arsenic contain 6.86 grains of phlogiston. From this experiment, three times repeated with the same success, our author proceeded to form, by calculation, a table of the absolute quantity of phlogiston contained in metals, the relative quantity having been computed by Mr Bergman, and his calculations adopted by our author. These quantities are as follow.

	Relative Quantity.	Absolute Quantity.
100 grains Gold	394	24.82
Copper	312	19.65
Cobalt	270	17.01
Iron	233	14.67
Zinc	182	11.46
Nickel	156	9.82
Regulus of } antimony }	120	7.56
Tin	114	7.18
Regulus of } arsenic }	109	6.86
Silver	100	6.30
Mercury	74	4.56
Bismuth	57	3.59
Lead	43	2.70

This point he likewise endeavoured to ascertain by other experiments. As silver loses a certain quantity of phlogiston, which escapes and separates from it during its solution in nitrous acid, he concluded, that if the solution was exposed to nothing from which it could reobtain phlogiston, and this was distilled to dryness, and entirely separated from the acid, as much silver should remain unreduced as corresponded with the quantity of phlogiston lost by it; and if this quantity corresponded with that in the above table, he then had good reason to conclude that the table was just.

For this purpose 120 grains of standard silver were dissolved in dephlogisticated nitrous acid diluted with water, and he obtained from it 24 cubic inches of nitrous air. This solution was gently evaporated to

dryness; and he found that, during the evaporation, about a quarter of a grain of the silver had been volatilized. The dry residuum was then distilled, and kept an hour in a coated green-glass retort heated almost to a white heat. Abundance of nitrous acid passed off during the operation, and a green and white sublimate rose into the neck of the retort, some of it even passing over into the receiver. On breaking the retort, the inside was penetrated with a yellow and red tinge, and partly covered over with an exceedingly fine silver powder, which could scarcely be scraped off. The remainder of the silver was white, and perfectly free from acid, but not melted into a button. On being collected, it weighed 94 grains; consequently 26 grains had been lost either by sublimation or vitrification; but of these 26 grains 9 were copper; for 100 grains of standard silver contain $7\frac{1}{2}$ of copper, therefore only 17 grains of pure silver remained unreduced, being either volatilized or vitrified. The whole quantity of pure silver in 120 grains of standard silver amounts to 111 grains; then if 111 grains of pure silver lose 17 by being deprived of its phlogiston, 100 grains of the same should lose 15.3; and by the above table 15.3 grains of silver should contain 0.945 of a grain of phlogiston. Now, 100 grains of pure silver afford 14 cubic inches of nitrous air, which, according to our author's calculation, contain 0.938 of a grain of phlogiston; and this differs from 0.945 only by .007 of a grain. "In this experiment (says Mr Kirwan) only as much of the silver sublimed as could not regain phlogiston; the remainder regained it from the nitrous air absorbed by the solution, and by that which remained in the acid and calx. If this were not so, I do not see why the whole of the silver would not sublime."

Dr Priestley having several times dissolved mercury in the nitrous acid, and revived it by distilling over that acid, constantly found a considerable portion of it unreduced. To try whether that proportion corresponded with his calculation, Mr Kirwan examined Dr Priestley's experiment, viz. that having dissolved 17 penny-weights 13 grains (321 grains) of mercury in nitrous acid, 36 grains remained unreduced. According to Mr Kirwan's calculation 56 grains should have remained unreduced; for 100 grains of mercury afford 12 cubic inches of nitrous air; of consequence 321 grains should afford 38.52, which contain 2.58 of phlogiston: and if, as according to the table, 4.56 grains of phlogiston be necessary to metallize 100 grains of mercury, 2.58 grains will be necessary to metallize 56 grains of the same metal; and our author is satisfied from his own trials, that more than 50 grains would have remained unreduced, if dephlogisticated nitrous acid had been used in dissolving the mercury, and the solution performed with heat and a strong acid: but that which the Doctor used was of the smoking kind, and consequently contained a considerable quantity of phlogiston already, which undoubtedly contributed to revive more of the metal than would otherwise have been done. It is true, Dr Priestley afterwards revived a great part of what had originally remained unreduced; but this happened after it had been some time exposed to the free air, from which the calces of metals always attract phlogiston; as is evident in luna cornea, which blackens on being exposed to the air.

By another experiment of Dr Priestley's, it was found,

Solution and Precipitation.

324 Of the revival of lead from minium by inflammable air.

325 Mr Kirwan's remarks on the experiments of Dr Priestley.

326 Of the attraction of metallic calces to phlogiston.

327 Of finding the specific gravity of the different metallic calces.

328 Whence their various degrees of affinity to phlogiston may be determined.

329 Of the affinity of calces to the deficient part of their phlogiston.

found, that nearly five pennyweights of minium, from whence all its air was extracted, that is, about 118 grains, absorbed 40 ounce-measures, or 75.8 cubic inches of inflammable air, containing 2.65 grains of phlogiston, by which they were reduced. An hundred grains of minium, therefore, require for their reduction nearly 2.25 grains of phlogiston. In another experiment made with more care, he found, that 480 grains of minium absorbed 108 ounce-measures of inflammable air: so that, according to this, 100 grains of minium require for their reduction 1.49 grains of phlogiston; and in two succeeding experiments he found the quantity still less. On this Mr Kirwan remarks, 1. That the whole of the minium was not dephlogisticated; for it is never equally calcined, and besides much of it must have been reduced during the expulsion of its air. 2. The quantity of phlogiston in the inflammable air may have been greater, as this varies with its temperature and the weight of the atmosphere: so that on the whole these experiments confirm the results expressed in the table.

Mr Kirwan next proceeds to consider the attraction of metallic calces to phlogiston. Inflammable air, when condensed into a solid substance, he supposes not only equal, but much superior, to any metallic calx in specific gravity; and therefore, if we could find the specific gravity of any calx free both from phlogiston and fixed air, we would thus know the density which phlogiston acquires by its union with such calx. It has, however, hitherto proved impossible to procure calces in such a state; as, during their dephlogistication, they combine with fixed air or some particles of the menstruum, whence their absolute weight is increased, and their specific gravity diminished. Hence it appears, that the specific gravity of the calces differs much less from that of their respective metals, than the specific gravity which the phlogiston requires by its union with those calces from that which it possesses in its uncombined state. Hence, instead of deducing the quantity of affinity betwixt phlogiston and metallic calces from the following proposition, that "the affinity of metallic calces to phlogiston is in a compound ratio of its quantity and density in each metal," he is obliged to deduce it from this other, that "the affinity of metallic calces to phlogiston is directly as the specific gravity of the respective metals, and inversely as the quantity of calx contained in a given weight of these metals." This latter proposition is an approximation to the former, founded on this truth, that "the larger

the quantity of phlogiston in any metal is, the smaller is the quantity of calx in a given weight of that metal;" and, that "the density which the phlogiston acquires is as the specific gravity of the metal." This latter proposition, however, is not strictly true, for this density is much greater; but its defect is only sensible with regard to those metals which contain a considerable quantity of phlogiston, as gold, copper, cobalt, and iron. With regard to the rest, it is of no importance. The specific gravity of the different metals, then, being as represented in the first column of the following table, the affinity of their calces to phlogiston will be as in the second; and the third expresses the affinities in numbers homogeneous with those which express the affinities of acids with their basis.

	Specific Gravity.	Proportionable Affinities.	Real Affinities of Calx to Phlogist.	330 Table of the proportional affinities of metallic calces to phlogiston.
Gold	19	0.25	1041	
Mercury	14	0.147	612	
Silver	11.091	0.118	491	
Lead	11.33	0.116	483	
Copper	8.8	0.109	454	
Bismuth	9.6	0.099	412	
Cobalt	7.7	0.092	383	
Iron	7.7	0.090	375	
Regulus of Arsenic	8.31	0.089	370	
Zinc	7.24	0.0812	338	
Tin	7	0.075	312	
Regulus of Antimony	6.86	0.074	308	

From this table we may see why lead is useful in cupellation; namely, because it has a greater affinity with phlogiston than the calces of any of the other imperfect metals; consequently after it has lost its own phlogiston, it attracts that of the other metals with which it is mixed, and thus promotes their calcination and vitrification.

The third point necessary for the explanation of the phenomena attending the solution of metals, and their precipitation by each other, is to determine the proportion of phlogiston which they lose by solution in each of the acids, and the affinity which their calces bear to the part so lost. Though our author was not able to determine this by any direct experiment, yet from various considerations he was led to believe that it was as follows:

Quantity of Phlogiston separated

	From Iron, Copper, Tin, Lead, Silver, Mercury, Zinc, Bismuth, Cobalt, Nickel, Reg. of Ant. Reg. of Arse.
By the vitriolic acid	$\frac{2}{3}$ $\frac{8}{10}$ $\frac{7}{10}$ $\frac{28}{100}$ Entire $\frac{87}{100}$ $\frac{85}{100}$ $\frac{85}{100}$ $\frac{93}{100}$ Entire $\frac{97}{100}$ $\frac{86}{100}$
By nitrous acid	$\frac{2}{3}$ $\frac{81}{100}$ $\frac{7}{10}$ $\frac{88}{100}$ Entire $\frac{9}{10}$ $\frac{99}{100}$ $\frac{97}{100}$ Entire Entire Entire $\frac{99}{100}$
By marine acid	$\frac{42}{100}$ $\frac{57}{100}$ $\frac{3}{10}$ $\frac{6}{10}$ — — — $\frac{7}{10}$ $\frac{94}{100}$ $\frac{8}{10}$ $\frac{84}{100}$ $\frac{8}{10}$

The affinity of the calces to the deficient part of their phlogiston may now be easily calculated; for they may be considered as acids, whose affinity to the deficient part of their basis is as the ratio which that part bears to the whole. Thus the affinity of iron, thoroughly deprived of its phlogiston, being 375, as it loses two-thirds of its phlogiston by solution in the vitriolic acid, the affinity of iron to these is two-thirds of its whole affinity; that is, two-thirds of 375, or 250.

Thus we may easily construct a table of the affinities of the phlogiston of different metals for their calces; and from this and that formerly given, by which the affinities of the acids to the metallic calces was expressed, we may guess what will happen on putting one metal in the solution of another. Thus if a piece of copper be put into a saturated solution of silver, the silver will be precipitated; for the balance is in favour of the divellent powers, as appears from the following calculation.

334
Of the ex-
cess of a-
cid in so-
lutions pro-
per for ma-
king these
experi-
ments.

In making these experiments the solutions must be nearly, though not entirely, saturated. If much superfluous acid be left, a large quantity of the added metal will be dissolved, before any precipitation can be made to appear; and when the solution is perfectly saturated, the attraction of the calces for one another begins to appear; a power which sometimes takes place, and which has not yet been fully investigated.

335
Why the
metals are
more de-
phlogisti-
cated by
mutual pre-
cipitation
than by di-
rect solu-
tion.

In this way the precipitating metals are more dephlogisticated than by direct solution in their respective menstrua; and are even dissolved by menstrua which would not otherwise affect them. The reason of this is, that their phlogiston is acted upon by two powers instead of one: and hence, though copper be directly soluble in the vitriolic acid only when in its concentrated state, and heated to a great degree; yet if a piece of copper be put into a solution of silver, mercury, or even iron, though dilute and cold, and exposed to the air, it will be dissolved; a circumstance which has justly excited the admiration of several eminent chemists, and which is inexplicable on any other principles than those just now laid down. From this circumstance we may see the reason why vitriol of copper, when formed by nature, always contains iron.

336
Why cop-
per is dis-
solved by
solution of
silver, mer-
cury, or i-
ron.

Mr Kirwan now proceeds to consider the solutions of metallic substances in all the different acids.

337
Iron and
zinc the
only metals
dissolved by
vitriolic a-
cid.

Vitriolic acid, he observes, dissolves only iron and zinc of all the metallic substances, because its affinity to their calces is greater than that which they bear to the phlogiston they must lose before they can unite with it.

338
Nitrous a-
cid dissolves
all metals,
though it
has less af-
finity with
them than
the vitrio-
lic or ma-
rine.

Nitrous acid has less affinity with all metallic substances than either the vitriolic or marine; yet it dissolves them all, gold, silver, and platina excepted, though it has even less affinity with them than they have with that portion of phlogiston which must be lost before they can dissolve in any acid. The reason of this is, that it unites with phlogiston, unless when in too diluted a state; and the heat produced by its union with phlogiston is sufficient to promote the solution of the metal. On the other hand, when very concentrated, it cannot dissolve them; because the acid does not then contain fire enough to throw the phlogiston into an aerial form, and reduce the solid to a liquid.

339
Why it
cannot dis-
solve them
when much
concentra-
ted.

The marine acid dephlogisticates metals less powerfully than any other. It can make no solution, or at least can operate but very slowly, without heat, in those cases where the metallic calx has a stronger affinity with that portion of the phlogiston which must be lost, than the acid: nor can it operate briskly even where the attraction is stronger, provided the quantity of acid be small; because such a little quantity of acid does not contain fire enough to volatilize the phlogiston: and hence heat is necessary to assist the marine acid in dissolving lead. When dephlogisticated, it acts more powerfully.

340
In what
cases the
marine a-
cid can dis-
solve me-
tals, and
when it
cannot.

It has been observed, that copper and iron mutually precipitate one another. If a piece of copper be

put into a saturated solution of iron fresh made, no precipitation will ensue for 12 hours, or even longer, if the liquor be kept close from the air; but if the liquor be exposed to the open air, the addition of volatile alkali will show, in 24 hours, that some of the copper has been dissolved, or sooner, if heat be applied, and a calx of iron is precipitated. The reason of this will be understood from the following state of the affinities.

Solution
and Preci-
pitation.
241
Why cop-
per and i-
ron preci-
pitate one
another.

<i>Quiescent.</i>		<i>Divellent.</i>	
Vitriolic acid to calx of iron	270	Vitriolic acid to copper	260
Copper to its phlogiston	360	Calx of iron to phlogiston	250
	630		510

In this case no decomposition can take place, because the sum of the divellent affinities is less than that of the quiescent; but in the second, when much of the phlogiston of the iron has escaped, the affinity of the calx of iron to the acid is greatly diminished, at the same time that the affinity of the calx to phlogiston is augmented. The state of the affinities may therefore be supposed as follows.

<i>Quiescent.</i>		<i>Divellent.</i>	
Vitriolic acid to calx of iron	240	Vitriolic acid to copper	260
Copper to its phlogiston	360	Calx of iron to phlogiston	370
	600		630

The increase of affinity of the calx of iron to phlogiston is not a mere supposition; for if we put some fresh iron to a solution of the metal so far dephlogisticated as to refuse to crystallize, so much of the phlogiston will be regained that the impoverished solution will now yield crystals. The reason why the increased quantity of phlogiston does not enable the acid to react upon the metal is, because it is neither sufficiently large, nor attracted with a sufficient degree of force, to which the access of air and heat employed contribute considerably. The diminution of attraction in calces of iron for acids is evident, not only from this but many other experiments; and particularly from the necessity of adding more acid to a turbid solution of iron in order to re-establish its transparency.

342
Increase of
the attrac-
tion of

stion de-
monstra-
ted.

A dephlogisticated solution of iron is also precipitated by the calces of copper. The same thing happens to a solution of iron in nitrous acid; only as the acid predominates greatly in this solution, some of the copper is dissolved before any of the iron is precipitated. Copper precipitates nothing from solution of iron in the marine acid, though exposed to the open air for 24 hours.

phlogisti-
cated solu-
tions of i-
ron.

Solution of copper in the vitriolic acid is instantly precipitated by iron; the reason of which is plain from the common table of affinities: and hence the foundation of the method of extracting copper, by means of iron, from some mineral waters. The precipitated solution affords a vitriol of iron, but of a paler kind than that commonly met with, and less fit for dyeing, as being more dephlogisticated: the reason of which is, that copper contains more phlogiston than iron: old iron is also used which has partly lost its phlogiston.

giston. Hence the iron is more dephlogisticated by precipitating copper than by mere dissolution in the vitriolic acid; and hence cast iron, according to the observations of Mr Schlutter, will scarcely precipitate a solution of copper; because it contains less phlogiston than bar-iron, as Mr Bergman has informed us.

Mr Kirwan always found silver easily precipitated by means of iron from its solution in nitrous acid; though Bergman had observed that a saturated solution of silver could not be thus precipitated without great difficulty, even though the solution were diluted and an excess of acid added to it. What precipitation took place could only be accomplished by some kinds of iron. The reason of this Mr Kirwan supposes to be, that the solution, even after it is saturated, takes up some of the silver in its metallic form; which Mr Scheele has also observed to take place in quicksilver. The last portions of both these metals, when dissolved in strong nitrous acid, afford no air, and consequently are not dephlogisticated. This compound of calx, therefore, and of silver in its metallic state, it may reasonably be supposed cannot be precipitated by iron, as the silver in its metallic form prevents the calx from coming into contact with the iron, and extracting the phlogiston from it; and for the same reason iron has been observed not to precipitate a solution of mercury in the nitrous acid.

Zinc cannot precipitate iron, as Mr Bergman has shown, until the solution of the latter loses part of its phlogiston. Hence we may understand why Newmann denied that iron can be precipitated by means of zinc. Mr Kirwan, however, has found, that zinc does not precipitate iron from the nitrous acid; but on the contrary, that iron precipitates zinc. In a short time the acid redissolves the zinc and lets fall the iron, owing to the calx of iron being too much dephlogisticated. Iron, however, will not precipitate zinc either from the vitriolic or marine acids. Most of the metallic substances precipitated by iron from the nitrous acid are in some measure redissolved shortly after; because the nitrous acid soon dephlogisticates the iron too much, then lets it fall, reacts on the other metals, and dissolves them.

Dr Lewis observes, that silver is sometimes not precipitated by copper from the nitrous acid; which happens either when the acid is supersaturated with silver by taking up some in its metallic form, or when the silver is not much dephlogisticated. In this case, the remedy is to heat the solution and add a little more acid, which dephlogisticates it further; but the nitrous acid always retains a little silver.

It has commonly been related by chemical authors, that blue vitriol will be formed by adding filings of copper to a boiling solution of alum. Mr Kirwan, however, has showed this to be an error: for after boiling a solution of alum for 20 hours with copper filings, not a particle of the metal was dissolved; the liquor standing even the test of the volatile alkali. The alum indeed was precipitated from the liquor, but still retained its saline form; so that the precipitation was occasioned only by the dissipation of the superfluous acid.

No metal is capable of precipitating tin in its metallic form; the reason of which, according to Mr Kirwan, is, because the precipitation is not the effect

of a double affinity, but of the single greater affinity of its menstruum to every other metallic earth. Metals precipitated from the nitrous acid by tin are afterwards redissolved, because the acid soon quits the tin by reason of its becoming too much dephlogisticated.

Lead precipitates metallic solutions in the vitriolic and marine acids but slowly, because the first portions of lead taken up form salts very difficult of solution, which cover its surface, and protect it from the further action of the acid; at the same time it contains so little phlogiston, that a great quantity of it must be dissolved before it will dissolve other metals. A solution of lead very much saturated cannot be precipitated by iron but with difficulty, if at all. Mr Kirwan conjectures that this may arise from some of the lead also being taken up in its metallic form, as is the case with mercury and silver. Iron will not precipitate lead from marine acid; for though a precipitate appears, the acid is still adhering to the metal. On the contrary, iron is precipitated from its solution in this acid by lead, though very slowly.

Mercury is quickly precipitated from the vitriolic acid by copper, though the difference between the sum of the quiescent and divellent affinities is but very small. The precipitation, however, takes place, because the calx of mercury has a strong attraction for phlogiston; and a very small portion of what is contained in copper is sufficient to revive it.

Silver, however, is not able to precipitate mercury from the vitriolic acid, unless it contains copper; in which case a precipitation will ensue: but on distilling silver and turpeth mineral, the mercury will pass over in its metallic form; which shows that the affinity of the calx of mercury to phlogiston is increased by heat, though the difference betwixt the divellent and quiescent powers is very small.

Mercury appeared to be precipitated by silver from the nitrous acid, though very slowly; but when the solution was made without heat, it was not at all precipitated. On the other hand, mercury precipitates silver from this acid, not by virtue of the superiority of the usual divellent powers, but by reason of the attraction of mercury and silver for each other; for they form partly an amalgam and partly a vegetation, scarcely any thing of either remaining in the solution.

Silver does not precipitate mercury from the solution of corrosive sublimate; but, on the contrary, mercury precipitates silver from the marine acid: and if a solution of *luna cornea* in volatile alkali be triturated with mercury, calomel will be formed; yet on distilling calomel and silver together, the mercury will pass in its metallic form, and *luna cornea* will be formed. The same thing happens on distilling silver and corrosive sublimate, the affinity of calx of mercury to phlogiston increasing with heat.

Bismuth precipitates nothing from vitriol of copper in 16 hours; nor does copper from vitriol of bismuth.

The two metallic substances, however, alternately precipitate one another from the nitrous acid, which proceeds from their different degrees of dephlogistication.

Nickel will scarcely precipitate any metal except it be reduced to powder. A black powder is precipitated by means of zinc from the solution of nickel

in the vitriolic and nitrous acids, which has been shown by Bergman to consist of arsenic, nickel, and a little of the zinc itself. The latter, however, precipitates nickel from the marine acid.

The solutions of iron and nickel in the vitriolic acid mutually act upon these metals; but neither of them will precipitate the other in 24 hours, though on remaining longer at rest iron seems to have the advantage. Iron, however, evidently precipitates nickel from the nitrous acid; and though nickel seems to precipitate iron, yet this arises only from the gradual dephlogistication of the iron.

Copper is precipitated in its metallic form from the vitriolic, nitrous, and marine acids, by nickel. The vitriolic and nitrous solutions of lead seem to act upon it without any decomposition, the calces uniting to each other. Lead seems for some time to be acted upon in the same manner by the vitriolic and nitrous solutions of nickel, but at last nickel seems to have the advantage; but a black precipitate appears whichever of them is put into the solution of the other. However, nickel readily precipitates vitriolic and nitrous solutions of bismuth; but in the marine acid both these semimetals are soluble in the solutions of each other: yet nickel precipitates bismuth very slowly, and only in part; while bismuth precipitates a red powder, supposed by Mr Kirwan to be ochre, from the solution of nickel.

Cobalt is not precipitated by zinc either from the vitriolic or nitrous acids, though it seems to have some effect upon it when dissolved in that of sea-salt.

Iron precipitates cobalt from all the three acids, yet much of the semimetal is retained in the vitriolic and nitrous solutions of it, particularly the latter; which, after letting fall the cobalt, takes it up again, and lets fall a dephlogisticated calx of iron. Nickel also, though it does not precipitate cobalt itself, as appears by the remaining redness of the solution, yet constantly precipitates some heterogeneous matter from it. Solution of cobalt in the marine acid becomes colourless by the addition of nickel. Bismuth is soluble in the vitriolic and nitrous solutions of cobalt, and throws down a small white precipitate, but does not affect the metallic part. Nor can we attribute these solutions in vitriolic acid to any excess in that acid, as they are dilute and made without heat. Copper also precipitates from the solution of cobalt a white powder supposed to be arsenic.

The regulus of antimony has no effect on solution of copper in vitriolic acid; nor is precipitated by it from the same acid; but it dissolves slowly in vitriol of antimony. With solution of vitriol of lead it becomes red in 16 hours, but is scarcely precipitated by lead from the vitriolic acid. Powdered regulus also precipitates vitriol of mercury very slightly. Bismuth neither precipitates nor is precipitated by the regulus in 24 hours from the vitriolic acid. Tin precipitates the regulus from the nitrous acid; but if regulus be put into a solution of tin in the same acid, neither of the metals will be found in the liquid in 16 hours, either by reason of the dephlogistication or of the union of the calces to each other.

Iron does not precipitate regulus of antimony entirely from the marine acid; but seems to form a triple salt, consisting of the acid and both calces.

N^o 71.

The regulus may also be dissolved by marine salt of iron.

Copper does not precipitate regulus of antimony from marine acid in 16 hours; and if the regulus be put into marine salt of copper, it will be dissolved, and volatile alkalies will not give a blue, but a yellowish white precipitate; so that here also a triple salt is formed.

Solution of arsenic in vitriolic acid acts upon iron, lead, copper, nickel, and zinc; but scarce give any precipitate: neither is arsenic precipitated by iron from the nitrous acid, though it is by copper, and even silver gives a slight white precipitate. Regulus of arsenic, however, precipitates silver completely in 16 hours: whence the former precipitate seems to be a triple salt. Mercury also slightly precipitates arsenic from the nitrous acid, and seems to unite with it, though it is itself precipitated by regulus of arsenic in 24 hours.

Bismuth slightly precipitates arsenic from spirit of nitre, but regulus of arsenic forms a copious precipitate in the nitrous solution of bismuth; so that Mr Kirwan is of opinion that the calces unite. It is not precipitated from this acid by nickel, but the calces unite. Though regulus of arsenic produces a copious precipitate in the solution of nickel in nitrous acid, yet the liquor remains green; so that the nickel is certainly not precipitated. The white precipitate in this case seems to be arsenic slightly dephlogisticated. Regulus of arsenic also produces a white precipitate in the nitrous solution of cobalt, but the liquor still continues red.

Regulus of arsenic is precipitated from the marine acid by copper; but the precipitate does not strike a blue colour with volatile alkali, because the metal unites with the arsenic. The arsenic is also precipitated by iron. Tin is soluble in marine solution of arsenic, but Mr Kirwan could not observe any precipitation; nor does regulus of arsenic precipitate tin. Neither bismuth nor regulus of arsenic precipitate each other from marine acid in 16 hours. Regulus of antimony is also acted upon by the marine solution of arsenic, though it causes no precipitate, nor does the regulus of arsenic precipitate it.

§ 2. *Of the Quantities of Acid, Alkali, &c. contained in different Salts, with the Specific Gravity of the Ingredients.*

It is a problem by which the attention of the best modern chemists has been engaged, to determine the quantity of acid existing in a dry state in the various compound salts, resulting from the union of acid with alkaline, earthy, and metallic substances. In this way Mr Kirwan has greatly excelled all others, and determined the matter with an accuracy and precision altogether unlooked for. His decisions are founded on the following principles.

1. That the specific gravity of bodies is their weight divided by an equal bulk of rain or distilled water; the latter being the standard with which every other body is compared.

2. That if bodies specifically heavier than water be weighed in air and in water, they lose in water part of the weight which they were found to have in air; and

&c. of the
Salts.

and that the weight so lost is just the same as that of an equal bulk of water; and consequently, that their specific gravity is equal to their weight in air, or absolute weight divided by their loss of weight in water.

3. That if a solid, specifically heavier than a liquid, be weighed first in air and then in that liquid, the weight it loses is equal to the weight of an equal volume of that liquid; and consequently, if such solid be weighed first in air, then in water, and afterwards in any other liquid, the specific gravity will be as the weight lost in it by such solid, divided by the loss of weight of the same solid in water. This method of finding the specific gravity of liquids, our author found more exact than that by the aerometer, or the comparisons of the weights of equal measures of such liquids and water, both of which are subject to several inaccuracies.

372
To find the weight of an equal bulk of water where the specific gravity is known.

4. That where the specific gravity of bodies is already known, we may find the weight of an equal bulk of water; it being as the quotient of their absolute weight divided by their specific gravities: and this he calls their loss of weight in water.

Thus where the specific gravity and absolute weight of the ingredients of any compound are known, the specific gravity of such compound may easily be calculated; as it ought to be intermediate betwixt that of the lighter and that of the heavier, according to their several proportions: and this Mr Kirwan calls the *mathematical specific gravity*. But in fact the specific gravity of compounds, found by actual experiment, seldom agrees with that found by calculation; but is often greater, without any diminution of the lighter ingredient. This increase of density, then, Mr Kirwan supposes to arise from a closer union of the component parts to each other than either had separately with its own integrant parts; and this more intimate union must, he thinks, proceed from the attraction of these parts to each other: for which reason he supposed, that this attraction might be estimated by the increase of density or specific gravity, and was proportionable to it; but soon found that he was mistaken in this point.

373
Mathematical specific gravity explained.

374
Increased density of mixtures accounted for.

375
Weights of different kinds of air.

With regard to the absolute weights of several sorts of air, our author adheres to the computations of Mr Fontana, at whose experiments he was present; the thermometer being at 55° , and the barometer at $29\frac{1}{2}$ inches, or nearly so. These weights were as follow:

Cubic inch of common air,	-	0.385
fixed air,	-	0.570
marine acid air,	-	0.654
nitrous air,	-	0.399
vitriolic acid air,	-	0.778
alkaline air,	-	0.2
inflammable air,	-	0.03

376
Method of finding the quantity of pure acid contained in spirit of salt.

Mr Kirwan begins his investigations with the marine acid; endeavouring first to find the exact quantity of pure acid it contains at any given specific gravity, and then by means of it determining the weight of acid contained in all other acids. For if a given quantity of pure fixed alkali were saturated, first by a certain quantity of spirit of salt, and then by determined quantities of the other acids, he concluded, that each of these quantities of acid liquor must contain the same quantity of acid; and this being known, the remain-

Vol. IV. Part II.

der, being the aqueous part, must also be known. This conclusion, however, rested entirely on the supposition that the same quantity of all the acids was requisite for the saturation of a given quantity of fixed alkali; for if such given quantity of fixed alkali might be saturated by a smaller quantity of one acid than of another, the conclusion fell to the ground. The weight of the neutral salts produced might indeed determine this point in some measure; but still a source of inaccuracy remained; to obviate which he used the following expedient. 1. He supposed the quantities of nitrous and vitriolic acids necessary to saturate a given quantity of fixed alkali exactly the same as that of marine acid, whose quantity he had determined; and to prove the truth of this supposition, he observed the specific gravity of the spirit of nitre and oil of vitriol he employed, and in which he supposed, from the trial with alkalies, a certain proportion of acid and water. He then added to these more acid and water, and calculated what the specific gravity should be on the above supposition; and finding the result agreeable with the supposition, he concluded the latter to be exact. The following experiments were made on the marine acid.

Two bottles were filled nearly to the top with distilled water, of which they contained in all 1399.9 grains, and successively introduced into two cylinders filled with marine air; and the process was renewed, until the water had imbibed, in 18 days, about 794 cubic inches of the marine air. The thermometer did not rise all this time above 55° ; nor sink, unless perhaps at night, above 50° ; the barometer standing between 29 and 30 inches. This dilute spirit of salt then weighed 1920 grains; that is, 520.1 more than before; the weight of the quantity of marine air absorbed. The specific gravity of the liquor was found to be 1.225. Its loss of weight in water (that is, the weight of an equal bulk of water) should then be 1567.346 nearly; but it contained only, as we have seen, 1399.9 grains of water: subtracting this therefore from 1567.346, the remainder (that is, 167.446) must be the loss of 520.1 grains of marine acid; and consequently the specific gravity of the pure marine acid, in such a condensed state as when it is united to water, must be $\frac{167.446}{520.1}$, or 3.100.

Still, however, it might be suspected, that the density of this spirit did not entirely proceed from the mere density of the marine acid, but in part also from the attraction of this acid to water; and though the length of time requisite to make the water imbibe this quantity of marine acid air, naturally led to the supposition that the attraction was not very considerable, yet the following experiment was more satisfactory. He exposed 1440 grains of this spirit of salt to marine acid air for five days, the thermometer being at 50° , or below; and then found that it weighed 1562 grains, and consequently had imbibed 122 grains more. Its specific gravity was then 1.253, which was precisely what it should have been by calculation.

Being now satisfied that the proportion of acid in spirit of salt was discovered, our author determined to find it in other acids also. For this purpose he took 180 grains of very strong oil of tartar *per deliquium*, and found that it was saturated by 180 grains of spirit of salt, whose specific gravity was 1.225; and by calculation

salts.

377
Method of finding the specific gravity of spirit of salt.

378
To find the proportion of pure air in other acid liquors.

Contents,
&c. of the
Salts.

calculation it appeared, that 180 grains of this spirit contained 48.7 grains of acid, and 131.3 of water. Hence he drew up a table of the specific gravities of acid liquors containing 48.7 grains of pure acid, with different proportions of water, from 50 to 410 parts; the liquor with the first proportion having a specific gravity of 1.497, and the latter weighing only 1.074. Mr Baume had determined the specific gravity of the strongest spirit of salt made in the common manner to be 1.187, and Bergman 1.190; but we are told in the Paris Memoirs for 1700, that Mr Homberg had produced a spirit whose specific gravity was 1.300; and that made by Dr Priestley, by saturating water with marine acid air, must have been about 1.500. The spirit of salt, therefore, whose specific gravity is 1.261, has but little attraction for water, and therefore attracts none from the air; for which reason also it does not heat the ball of a thermometer, as the vitriolic and nitrous acids do; though Mr Cavallo found that this also had some effect upon the thermometer. Common spirit of salt, Mr Kirwan informs us, is always adulterated with vitriolic acid, and therefore unfit for these trials.

379
Quantities
of acid, wa-
ter, and al-
kali, in di-
gestive salt.

Mr Kirwan now set about investigating the quantity of acid, water, and fixed alkali, in digestive salt, or a combination of the marine acid with vegetable alkali. For this purpose he took 100 grains of a solution of tolerably pure vegetable alkali, that had been three times calcined to whiteness, the specific gravity of which was 1.097; diluting also the spirit of salt with different portions of water; the specific gravity of one sort being 1.015, and of another 1.098. He then found that the above quantity of solution of the vegetable alkali required for its saturation 27 grains of that spirit of salt whose specific gravity was 1.098, and 23.35 grains of that whose specific gravity was 1.115. Now, 27 grains of spirit of salt, whose specific gravity is 1.098, contain 3.55 grains of marine acid, as appears by calculation. The principles on which calculations of this kind are founded, our author gives in the words of Mr Cotes.

380
How to find
the specific
gravities of
the different
ingredients.

"The data requisite are the specific gravities of the mixture and of the two ingredients. Then, as the difference of the specific gravities of the mixture and the lighter ingredient is to the difference of the specific gravities of the mixture and the heavier ingredient; so is the magnitude of the heavier to the magnitude of the lighter ingredient. Then, as the magnitude of the heavier, multiplied into its specific gravity, is to the magnitude of the lighter multiplied into its specific gravity; so is the weight of the heavier to the weight of the lighter. Then, as the sum of these weights is to the weight of either ingredient; so is the weight given to the weight of the ingredient sought." Thus, in the present case, $1.098 - 1.000 = .098$ is the magnitude of the heavier ingredient, viz. the marine acid, and $.098 \times 3.100 = 0.3038$ the weight of the marine acid; and on the other hand, $3.100 - 1.098 = 2.002$, the magnitude of the water; and $2.002 \times 1.000 = 2.002$ its weight; the sum of these weights is 2.3058: then if 2.3058 parts of spirit of salt contain 0.3038 parts acid, 27 grains of this spirit of salt will contain 3.55 acid. In the same manner it will be found, that 23.35 grains of spirit of salt, whose specific gravity is 1.115, contains 3.55 grains acid.

Our author describes very particularly his method of

making the saturation of the alkali with the acid; which, as it is always difficult to hit with precision, we shall here transcribe. "It was performed by putting the glass cylinder which contained the alkaline solution on the scale of a very sensible balance, and at the same time weighing the acid liquor in another pair of scales; when the loss of weight indicated the escape of nearly equal quantities of fixed air contained in the solution. Then the acid was gradually added by dipping a glass rod in it, to the top of which a small drop of acid adhered. With this the solution was stirred, and very small drops taken up and laid upon bits of paper stained blue with radish juice. As soon as the paper was in the least reddened, the operation was completed; so that there was always a very small excess of acid, for which half a grain was constantly allowed; but no allowance was made for the fixed air, which always remains in the solution. But as on this account only a small quantity of the alkaline solution was used, this proportion of fixed air must have been inconsiderable. If an ounce of the solution had been employed, this inappreciable portion of fixed air would be sufficient to cause a sensible error; for the quantity of fixed air lost by the difference betwixt the weight added to the 100 grains and the actual weight of the compound was judged of; and when this difference amounted to 2.2 grains, the whole of the fixed air was judged to be expelled: and it was found to be so; as 100 grains of the alkaline solution, being evaporated to dryness, in the heat of 300° , left a residuum which amounted to $10\frac{1}{2}$ grains, which contained 2.2 grains of fixed air."

The result of this experiment was, that 8.3 grains of pure vegetable alkali, freed from fixed air and water, or 10.5 of mild fixed alkali, were saturated by 3.55 grains of pure marine acid; and consequently the resulting neutral salt should, if it contained no water, weigh 11.85 grains: but the salts resulting from this union (the solution being evaporated to perfect dryness in a heat of 160 degrees, kept up for four hours) weighed at a medium 12.66 grains. Of this 11.85 grains were acid and alkali; therefore the remainder, viz. 0.81 grains, were water. An hundred grains of perfectly dry digestive salt contain 28 grains acid, 6.55 of water, and 65.4 of fixed alkali.

In his experiments on the nitrous acid, Mr Kirwan made use only of the dephlogisticated kind, which appears pure and colourless as water. "This pure acid (says he) cannot be made to exist in the form of air, as Dr Priestley has shown; for when it is deprived of water and phlogiston, and furnished with a due proportion of elementary fire, it ceases to have the properties of an acid, and becomes dephlogisticated air. Its proportion therefore could not be determined in spirit of nitre as the marine acid had been in spirit of salt in the last experiment."—To determine the matter, the following experiments were made.

1. To 1963.25 grains of dephlogisticated spirit of nitre, whose specific gravity was 1.419, he gradually added 179.5 grains of distilled water; and when it cooled, the specific gravity of the mixture was found to be 1.389.

2. To 1984.5 of this 178.75 grains of water were then added, and the specific gravity of the mixture found to be 1.362.

3. An hundred grains of a solution of fixed vegetable

fic gravity
of this acid

table alkali, whose specific gravity was 1.097, the same that had been formerly used in the experiments with spirit of salt, was found to be saturated by 11 grains of the spirit of nitre, whose specific gravity was 1.419, by 12 of that whose specific gravity was 1.389, and by 13.08 of that whose specific gravity was 1.362. These quantities were the medium of five experiments; and it was found necessary to dilute the acid with a small quantity of water. When this was neglected, part of the acid was phlogisticated, and flew off with the fixed air. Ten minutes were also allowed after each affusion for the matters to unite; a precaution which was likewise found to be absolutely necessary.

Upon the supposition, therefore, that a given quantity of vegetable fixed alkali is saturated by the same weight of both acids, we see that 11 grains of spirit of nitre, whose specific gravity is 1.419, contain the same quantity of acid with 27 grains of spirit of salt, whose specific gravity is 1.098, or 3.55 grains. The remainder of 11 grains, or 7.45 grains, is therefore mere water; and of consequence, if the density of the acid and water had not been increased by their union, the specific gravity of the pure nitrous acid should be 1.18729. But the specific gravity of the nitrous, as well as of the vitriolic acid, is augmented by its union with water; and therefore the loss of its weight in water is not exactly, as it would appear by calculation from the above premises, according to the rules already laid down. To determine therefore the real specific gravity of the acid in its natural state, the quantity of *accrued* density must be found, and subtracted from the specific gravity of the spirit of nitre, whose true mathematical specific gravity will then appear. This our author endeavoured to effect by mixing different portions of spirit of nitre and water, remarking the degree of diminution they sustained by such union; but was never able to attain a sufficient degree of exactness in the experiment. He had recourse therefore to the following method, as affording more satisfaction, though not altogether accurate. Twelve grains of the spirit of nitre, whose specific gravity by observation was 1.389, contained, as our author supposed from the former experiment, 3.55 grains of real acid, and 8.45 of water: then if the specific gravity of the pure nitrous acid were 1.1872, that of this compound acid and water should be 1.371; for the loss of 3.55 should be 0.299, and the loss of the water

8.45, the sum of the losses 8.749. Now, $\frac{12}{8.749} = 1.371$: but the specific gravity, as already mentioned, was 1.389; therefore the accrued density was at least 0.18. the difference betwixt 1.389 and 1.371. This calculation indeed is not altogether exact; but our author concludes, that 0.18 is certainly a near approximation to the degree of density that accrues to 3.55 grains of acid by their union to 7.45 grains of water: therefore, subtracting this from 1.419, we have nearly the mathematical specific gravity of that proportion of acid and water, namely, 1.401.

Again, since 11 grains of this spirit of nitre contain 3.55 grains acid, and 7.45 of water, its loss of weight should be $\frac{11}{1.401} = 7.855$; and subtracting the loss of the aqueous part from this, the remainder 0.45 is the

loss of the 3.55 grains acid; and consequently the true specific gravity of the pure and mere nitrous acid is $\frac{3.55}{0.405} = 8.7654$. This being settled, the mathematical

specific gravity and true increase of density of the above mixtures will be found. Thus the mathematical specific gravity of 12 grains of that spirit of nitre, whose specific gravity, by observation, was 1.389, must be 1.355; supposing it to contain 3.55 grains acid and 8.45 of water. For the loss of 3.55 grains acid is $\frac{3.55}{8.763} = 0.405$, and the loss of water 8.45; the sum of these losses is 8.855. Then $\frac{12}{8.855} = 1.355$; and

consequently the accrued density is $1.389 - 1.355 = 0.034$. In the same manner it will be found that the mathematical specific gravity of 13.08 grains of that spirit of nitre, whose specific gravity by observation was 1.362, must be 1.315; and consequently its accrued density .047.

The whole of this, however, still rests on the supposition that each of these portions of spirit of nitre contain 3.55 grains of acid. To verify this supposition, our author examined the mathematical specific gravities of the first mixture he had made of spirit of nitre and water in large quantities; for if the mathematical specific gravities of these agreed exactly with those of the quantities he had supposed in smaller portions of each, he could not but conclude that the suppositions of such proportions of acid and water, as he had determined in each, were just.

This being determined by proper calculations, Mr Kirwan next proceeded to construct another table of specific gravities, continuing his mixtures till the mathematical specific gravities found by observation nearly coincided with those made by calculation. In this table the spirit of nitre was mixed with water in various proportions, but after a different manner from that observed with the spirit of salt. Nine grains of the spirit containing 3.55 grains of pure acid were mixed with 5.45 of water; the accrued density of the mixture was found to be nothing, the mathematical specific gravity 1.537, and the specific gravity by observation was found the same. When 10 grains of spirit were mixed with 6.45 of water, the accrued density was 0.009, the mathematical specific gravity 1.458, and the specific gravity by observation 1.467. In this manner he proceeded until 38.90 grains of water were mixed with 42.45 of spirit. In this case the accrued density was found to be 0.002, the mathematical specific gravity 1.080, and the specific gravity by observation 1.082.

The intermediate specific gravities, in a table of this kind, may be found by taking an arithmetical mean betwixt the specific gravities, by observation, betwixt which the desired specific gravity lies, and noting how much it exceeds or falls short of such arithmetical mean; and then taking also an arithmetical mean betwixt the mathematical specific gravities betwixt which that sought for must lie, and a proportionate excess or defect.

The specific gravity of the strongest spirit of nitre yet made, is, according to Mr Baume, 1.500, and according to Mr Bergman 1.586.

Our author next proceeded to examine the proportion

tion of acid, water, and fixed alkali in nitre, in a manner similar to what he had already done with digestive salt; and found that 100 grains of perfectly dry nitre contained 28.48 grains of acid, 5.2 of water, and 66.32 of fixed alkali.

Some experiments of the same kind had been made by M. Homberg; the results of which our author compared with those of his own. The specific gravity of the spirit of nitre which M. Homberg made use of was 1.349; and of this, he says, one ounce two drachms and 36 grains, or 621 troy grains, are required to saturate one French ounce (472.5 troy) of dry salt of tartar. According to Mr Kirwan's computation, however, 613 grains are sufficient; for the specific gravity lies between the specific gravities by observation 1.362 and 1.337, and is nearly an arithmetical mean between them. The corresponding mathematical specific gravity lies between the quantities marked in Mr Kirwan's table 1.315 and 1.286, being nearly 1.300. Now the proportion of acid and water in this is 2.629 of acid and 7.465 of water; for $8.765 - 1.300 = 7.465$ of water, and $8.765 \times .300 = 2.629$ of acid; and the sum of both is 10.044. Now, since 10.5 grains of mild vegetable alkali require 3.53 grains of acid for their saturation, 472.5 will require 159.7; therefore if 10.044 grains of nitre contain 2.629 grains acid, the quantity of this spirit of nitre requisite to give 159.7 will be 613.2 nearly, and thus the difference with M. Homberg is only about eight grains.

M. Homberg says he found his salt, when evaporated to dryness, to weigh 186 grains more than before; but by Mr Kirwan's experiment, it should weigh but 92.8 grains more than at first; the cause of which difference will be mentioned in treating of vitriolated tartar, as it cannot be entirely attributed to the difference of evaporation.

He also asserts, that one ounce (472.5 Troy grains) of this spirit of nitre contains 141 grains of Troy of real acid. According to Mr Kirwan's computation, however, it contains only 123.08 grains of real acid. But this difference evidently proceeds from his neglecting the quantity of water that certainly enters into the composition of nitre; for he proceeds on this analogy, $621 : 186.6 :: 472.5 : 141$.

Our author observes, that the proportion of fixed alkali assigned by him to nitre is fully confirmed by an experiment of Mr Fontana's inserted in Rozier's Journal for 1778. He decomposed two ounces of nitre by distilling it with a strong heat for 18 hours. After the distillation there remained in the retort a substance purely alkaline, amounting to 10 French drachms and 22 grains. Now two French ounces contain 945 grains Troy, and the alkaline matter 607 grains of the same kind: according to Mr Kirwan's computation the two ounces of nitre ought to contain 625 grains of alkali. Such a small difference he supposes to proceed from the loss in transferring from one vessel to another, weighing, filtering, evaporating, &c. Mr Kirwan also shows in a very particular manner the agreement of his calculations with the experiments of M. Lavoisier on mercury dissolved in spirit of nitre; but our limits will not allow us to insert an account of them.

When finding the quantity of pure acid contained in oil of vitriol, our author made use of such as was not dephlogisticated; but, though pale, yet a little in-

clining to red. It contained some whitish matter, as he perceived by its growing milky on the affusion of pure distilled water; but he imagines it was as pure as the kind used in all experiments.

To 2519.75 grains of this oil of vitriol, whose specific gravity was 1.819, he gradually added 180 grains of distilled water, and six hours after found its specific gravity to be 1.771.—To this mixture he again added 178.75 grains of water, and found its specific gravity, when cooled to the temperature of the atmosphere, to be 1.719, at which time it was milky. The same quantity of the oil of tartar above mentioned was then saturated with each of these kinds of oil of vitriol in the manner already described. The saturation was effected (taking a medium of five experiments) by 6.5 grains of that whose specific gravity was 1.819, by 6.96 grains of that whose specific gravity was 1.771, and by 7.41 of that whose specific gravity was 1.719.

It was found necessary to add a certain proportion of water to each of these sorts of oil of vitriol; for when they were not diluted, part of the acid was dephlogisticated, and went off with the fixed air; but knowing the quantity of water that was added, it was easy to find by the rule of proportion the quantity of each sort of vitriol that was taken up by the alkali. Hence it was supposed, that each of these quantities of oil of vitriol of different densities contained 3.55 grains of acid; as they saturated the same quantity of vegetable fixed alkali with 11 grains of spirit of nitre, which contained that quantity of acid.

It was next attempted to find the specific gravity of the pure vitriolic acid, in a manner similar to that by which the gravity of the nitrous acid was found; as it cannot be had in the shape of air, unless when united with such a quantity of phlogiston as quite alters its properties. The loss of 6.5 grains of oil of vitriol, whose

specific gravity is 1.819, is $\frac{6.5}{1.819} = 3.572$; but as these 6.5 grains contained, besides 3.55 of acid, 2.95 of water, the loss of this must be subtracted from the entire loss; and then the remainder, or 0.622, is the loss of the pure acid part in that state or density to which it is reduced by its union with water. The specific gravity, therefore, of the pure vitriolic acid, in

this state of density, is $\frac{3.55}{0.622} = 5.707$. But to find its natural specific gravity, we must find how much its density is increased by its union with this quantity of water: and in order to observe this, he proceeded as before with the nitrous acid. 6.96 grains of oil of vitriol, whose specific gravity was 1.771, contained 3.55 of acid and 3.41 of water; then its specific gravity by calculation should be 1.726; for the loss of

3.55 grains of acid is $\frac{3.55}{5.707} = 0.622$; the loss of 3.41 grains of water is 3.41; the sum of the losses 4.032: then $\frac{6.96}{4.032} = 1.716$; therefore the accrued density is 1.771

—1.726 = 0.45.—Taking this therefore from 1.819, its mathematical specific gravity will be 1.774. Then the loss of 6.5 grains of oil of vitriol, whose specific gravity by observation is 1.819, will be found to be

$\frac{6.5}{1.774} = 3.663$; but of this, 2.95 grains are the loss

Contents,
&c. of the
Salts

of the water it contains, and the remainder 0.714 are the loss of the mere acid part. Then $\frac{3.55}{0.714}$ is nearly the true specific gravity of the pure vitriolic acid. The specific gravity of the most concentrated oil of vitriol yet made, is, according to M. Baume and Bergman, 2.125.

398
Quantity of
acid, alkali,
and water,
in vitriola-
ted tartar
determined

Mr Kirwan now constructed a table of the specific gravities of vitriolic acids, of different strengths, in a manner similar to those constructed for spirit of salt and spirit of nitre; but for which, as well as the others, we must refer to Phil. Trans. vol. 71. He then proceeded to find the proportion of acid, water, and fixed alkali, in vitriolated tartar, as he had before done in sal digestivus and nitre.—He found the salts resulting from the saturation of the same oil of tartar, with portions of oil of vitriol, of different specific gravities, to weigh at a medium 12.45 grains. Of this weight only 11.85 grains were alkali and acid. The remainder, therefore, was water, viz. 0.6 of a grain. Consequently 100 grains of perfectly dry tartar vitriolate contain 21.58 grains acid, 4.82 of water, and 66.67 of fixed vegetable alkali.—In drying this salt, a heat of 240 degrees was made use of, to expel the adhering acid more thoroughly. It was kept in this heat for a quarter of an hour.

399
Difference
with Mr
Homberg
accounted
for.

According to Mr Homberg, one French ounce, or 472.5 grains troy, of dry salt of tartar, required 297.5 grains troy, of oil of vitriol, whose specific gravity was 1.674, to saturate it: but by Mr Kirwan's calculation, this quantity of fixed alkali would require 325 grains; a difference which, considering the different methods they made use of for determining the specific gravities (Homberg's method by mensuration, giving it always less than Mr Kirwan's) the different desiccation of their alkalies, &c. may be accounted inconsiderable.

The salt produced, according to Mr Homberg, weighed 182 grains troy above the original weight of the fixed alkali; but by Kirwan's experiment, it should weigh but 87.7 grains more. "It is hard to say (adds Mr Kirwan) how Mr Homberg could find this great excess of weight, both in nitre and tartar vitriolate; unless he meant by the weight of the salt of tartar the weight of the mere alkaline part distinct from the fixed air it contained: and indeed one would be tempted to think he did make the distinction; for in that case the excess of weight would be nearly such as he determined it."

From Mr Homberg's calculations, he inferred that one ounce (472.5 grains) of oil of vitriol contains 291.7 grains of acid. Mr Kirwan computes the acid only at 213.3 grains; but Homberg made no allowance for the water contained in tartar vitriolate; and imagined the whole increase of weight proceeded from the acid that is united in it to the fixed alkali. Now the aqueous part in 560 grains of tartar vitriolate amounts to 37 grains; the remaining difference may be attributed to the different degrees of desiccation, &c.

400
Specific
gravity of
the acetous
acid.

On the acetous acid Mr Kirwan did not make any experiment; but by calculating from those of Homberg, he finds that the specific gravity of the pure acetous acid, free from superfluous water, should be 2.30. "It is probable (says Mr Kirwan), that its affinity to water is not strong enough to cause any irregular increase in its density; at least what can be

expressed by three decimals: and hence its proportion of acid and water may always be calculated from its specific quantity and absolute weight."

Contents,
&c. of the
Salts.

An hundred parts of foliated tartar, or, as it should rather be called, acetous tartar, contain, when well dried, 32 of fixed alkali, 19 of acid, and 49 parts of water.—The specific gravity of the strongest concentrated vinegar yet made is 1.069.—It is more difficult to find the point of saturation with the vegetable than with the mineral acids, because they contain a mucilage that prevents their immediate union with alkalies; and hence they are commonly used in too great quantity: they should be used moderately hot, and sufficient time allowed them to unite.

From all the experiments above related, Mr Kirwan concludes, 1. That the fixed vegetable alkali takes up an equal quantity of the three mineral acids, and probably of all pure acids; for we have seen that 8.3 grains of pure vegetable alkali, that is, free from fixed air, take up 3.55 grains of each of these acids; and consequently 100 parts of caustic fixed alkali would require 42.4 parts of acid to saturate them. But Mr Bergman has found that 100 parts of caustic fixed vegetable alkali take up 47 parts of the aerial acid; which, considering that his alkali might contain some water, differs but little from that already given. It should seem, therefore, that alkalies have a certain determined capacity of uniting to acids, that is, to a given weight of acids; and that this capacity is equally satiated by a given weight of any pure acid indiscriminately. This weight is about 2.35 of the vegetable alkali.

2. That the three mineral acids, and probably all pure acids, take up 2.253 times their own weight of pure vegetable alkali, that is, are saturated by that quantity.

3. That the density accruing to compound substances, from the union of their compound parts, and exceeding its mathematical ratio, increases from a minimum, when the quantity of one of them is very small in proportion to that of the other; to a maximum, when their qualities differ less: but that the attraction, on the contrary, of that part which is in the smallest quantity to that which is in the greater, is at its maximum when the accrued density is at its minimum; but not reciprocally: and hence the point of saturation is probably the maximum of density and the minimum of sensible attraction of one of the parts. Hence no decomposition operated by means of a substance that has a greater affinity with one part of a compound than with the other, and than these parts have with each other, can be complete, unless the minimum affinity of this third substance be greater than the maximum affinity of the parts already united. Hence also few decompositions are complete, unless a double affinity intervenes; and hence the last portions of the separated substance adhere so obstinately to that with which it was first united, as all chemists have observed.—Thus, though acids have a greater affinity to phlogiston than the earths of the different metals have to it, yet they can never totally dephlogistificate these earths but only to a certain degree; so, though atmospheric air, and particularly dephlogisticated air, attracts phlogiston more strongly than the nitrous acid does, yet not even dephlogisticated air can deprive the nitrous acid totally of its phlogiston; as is evident from

the red colour of the nitrous acid, when nitrous air and dephlogisticated air are mixed together. Hence mercury precipitated from its solution in any acid, even by fixed alkalies, constantly retains a portion of the acid to which it was originally united, as Mr Bayen has shown. Thus also the earth of alum, when precipitated in like manner from its solution, retains part of the acid; and thus several anomalous decompositions may be explained.

4. That concentrated acids are in some measure phlogisticated, and evaporate by union with fixed alkalies. 5. That, knowing the quantity of fixed alkali in oil of tartar, we may determine the quantity of real pure acid in any other acid substance that is difficultly decomposed; as the sedative acid, and those in vegetables and animals. For 10.5 grains of the mild alkali will always be saturated by 3.55 grains of real acid; and reciprocally, the quantity of acid in any acid liquor being known, the quantity of real alkali in any vegetable alkaline liquor may be found.

Having thus determined the quantity of acid contained in the liquids of that kind usually employed in chemistry, as well as the specific gravities of the acids themselves, Mr Kirwan became desirous of investigating the gravity of fixed and volatile alkalies. But as these substances are not easily preserved from uniting themselves with fixed air, he was led to consider the gravity of this in its fixed state, as an element necessary for the calculation of the quantities of the alkalies.

To find the specific gravity of the fixed vegetable alkali, our author proceeded in a manner similar to that already described, excepting that he weighed it in ether instead of spirit of wine. The results of his experiments are,

1. That 100 grains of this alkali contain about 6.7 grains of earth; which, according to Mr Bergman, is siliceous. It passes the filter along with it when the alkali is not saturated with fixed air; so that it seems to be held in solution in the same manner as in the liquor silicum.

2. The quantity of fixed air in oil of tartar and dry vegetable fixed alkali is various at various times, and in various parcels of the same salt; but in the purer alkalies it may be reckoned at a medium 21 grains in 100; and hence the quantity of this alkali may very nearly be guessed at in any solution, by adding a known weight of any dilute acid to a given weight of such a solution, and then weighing it again; for as 21 is to 100, so is the weight lost to the weight of mild alkali in such solution. The specific gravity of mild and perfectly dry vegetable fixed alkali, four times calcined, free from siliceous earth, and containing 21 per cent. of fixed air, was found to be 5.0527. When it contains more fixed air the gravity is probably higher, except when it is not perfectly dry; and hence the specific gravity of this alkali, when caustic, was supposed by Mr Kirwan to be 4.234. For this reason the fixed alkalies, when united to aerial acid, are specifically heavier than when united either to the vitriolic or nitrous. Thus

Mr R. Watson, in the Philosophical Transactions for 1770, informs us, that he found the specific gravity of dry salt of tartar, including the siliceous earth it naturally contains, to be 2.761; whereas the specific gravity of vitriolated tartar was only 2.636, and that of nitre 1.933. The reason why nitre is so much lighter than

tartar vitriolate is, that it contains much more water, and the union of the acid with the water is less intimate.

Impure vegetable fixed alkalies, such as pearl-ash, pot-ashes, &c. contain more fixed air than the purer kind.

According to Mr Cavendish, pearl-ash contains 28.4 or 20.7 per cent. of fixed air. Hence in lyes made from these salts, of equal specific gravities with those of a purer alkali, the quantity of saline matter will probably be in the ratio of 28.4 or 28.7 to 21; but this additional weight is only fixed air. Much also depends on their age; the oldest containing most fixed air. Our author also gives a table of the specific gravities of different solutions of vegetable fixed alkali, in a manner similar to what he had done before with the acids. He begins with 64.92 grains of a solution containing 26.25 grains of salt, and 38.67 of water. The accrued density he finds to be .050, the mathematical specific gravity 1.445, and the specific gravity by observation 1.495. By continually diluting the solution containing the same quantity of salt, he brings the absolute weight of it at last to 341.94 grains, of which 317.49 are water; the accrued density 0.01, the mathematical specific gravity 1.061, and the specific gravity by observation 1.062.

In a subsequent paper on this subject, Philosophical Transactions, vol. 72, p. 179, our author corrects a small mistake concerning the quantity of acid taken up by 10.5 grains of mild vegetable alkali. In his former computations he had made no allowance for the small quantity of earth contained in this quantity of alkali; which, though inconsiderable in it, becomes of consequence where the quantities are large. The error, however, occasioned by this omission, is sensible in his calculations concerning the quantities of acid, alkali, &c. contained in the neutral salts, as well as in that concerning the vegetable alkali. When the correction is properly made, he says, it will be found that 100 grains of such alkali, free from earth, water, and fixed air, take up 46.77 of the mineral acids, that is, of the mere acid part; and 100 grains of common mild vegetable alkali take up 36.23 grains of real acid. An hundred grains of perfectly dry tartar vitriolate contain 30.21 of real acid, 64.61 of fixed alkali, and 5.18 of water. Crystallized tartar vitriolate loses only one per cent. of water in a heat in which its acid is not separated in any degree; and therefore contains 6.18 of water. An hundred grains of nitre, perfectly dry, contain 30.86 of acid, 66 of alkali, and 3.14 of water; but in crystallized nitre the proportion of water is somewhat greater; for 100 grains of these crystals being exposed to a heat of 180° for two hours, lost three grains of their weight without exhaling any acid smell; but when exposed to a heat of 200 degrees, the smell of the nitrous acid is distinctly perceived. Hence 100 grains of crystallized nitre contain 29.89 of mere acid, 63.97 of alkali, and 6.14 of water. An hundred grains of digestive salt perfectly dry, contain 29.68 of marine acid, 63.47 of alkali, and 6.85 of water. One hundred grains of crystallized digestive salt lose but one grain of their weight before the smell of the marine acid is perceived; and hence they contain 7.85 grains of water.

Another mistake, more difficult to be corrected, was his supposing the mixtures of oil of vitriol and water, and spirit of nitre and water, had attained their maximum of density when they had cooled to the temperature

ture of the atmosphere; which at the time he made the experiment was between 50° and 60° of Fahrenheit. The mixture with oil of vitriol had been suffered to stand six hours; but when the acid was so much diluted as to occasion little or no heat, it was allowed to stand only for a very little time. Several months afterwards, however, many of these mixtures were found much denser than when he first examined them; and it was discovered, that at least twelve hours rest was necessary before concentrated oil of vitriol, to which even twice its weight of water is added, can attain its utmost density; and still more when a smaller proportion of water is used. Thus when he made the mixture of 2519.75 grains of oil of vitriol, whose specific gravity was 1.819, with 180 of water, he found its density six hours after 1.771, but after 24 hours it was 1.798: and hence, according to the methods of calculating already laid down, the accrued density was at least .064 instead of .045. But by using oil of vitriol still more concentrated, whose specific gravity was 1.8846, he was enabled to make a still nearer approximation; and found, that the accrued density of oil of vitriol, whose specific gravity is 1.819, amounts to 0.104, and consequently its mathematical specific gravity is 1.715. Six grains and a half of this oil of vitriol contained, as has been already observed, 3.55 of mere acid, and the remainder was water. The weight of an equal bulk of water is 3.79 grains; and subtracting from this the weight of the water that enters into the composition of the oil of vitriol, it will be found, that the weight of a bulk of water equal to the acid part is 0.84; and consequently the specific gravity of the mere acid part is 4.226. Thus, by constantly allowing the mixtures to rest at least 12 hours, until the oil of vitriol was diluted with four times its weight of water, and then only six hours before the density of the mixtures was examined, he constructed another table, in which 1000 grains of liquor contained 612.05 of pure acid, 387.95 of water, the accrued density being .07, and the mathematical specific gravity 1.877. Increasing the quantity of water till the acid weighed 7000 grains, and the water 6387.95, he found the accrued density .059, and the mathematical specific gravity 1.069. By a similar correction of his experiments on the acid of nitre, he found its density to be 5.530; a similar table was constructed for it, for which we refer our readers to the 72d volume of the Philosophical Transactions.

423
Attestation
of the den-
sity of acids
by various
degrees of
heat.

These experiments were made when the thermometer stood between 50° and 60° of Fahrenheit; but, as it might be suspected that the density of acids is considerably altered at different degrees of temperature, he endeavoured to find the quantity of this alteration in the following manner: To calculate what this density would be at 55° , he took some dephlogisticated spirit of nitre, and examined its specific gravity at different degrees of heat; which was found to be as follows,

Degrees of heat.	Specific gravity.
30	1.4653
46	1.4587
86	1.4302
120	1.4123

The total expansion of this spirit of nitre, therefore, from 30 to 120 degrees, that is, by 90° of heat, was 0.0527; for $1.4650 = 4123 + .0527$. By which we see,

that the dilatations are nearly proportional to the degrees of heat: for beginning with the first dilatation from 30 to 46 degrees, that is, by 16 degrees of heat, we find that the difference between the calculated and observed dilatations is only $\frac{1}{1000}$; a difference of no consequence in the present case, and which might arise from the immersion of the cold glass-ball filled with mercury in the liquor. In the next case the difference is still less, amounting only to $\frac{1}{10000}$.

With another, and somewhat stronger spirit of nitre, the specific gravities were as follow:

Degrees of heat.	Specific gravity.
34	1.4750
49	1.4653
150	1.3792

Here also the expansions were nearly proportional to the degrees of heat; for 116° of heat, the difference between 34 and 150, produce an expansion of 0.0958; and 15° of heat, the difference between 34 and 49, produce an expansion of 0.0097; and by calculation 0.0123: which last differs from the truth only by $\frac{1}{10000}$.

From this experiment we see, that the stronger the spirit of nitre is, the more it is expanded by the same degree of heat; for if the spirit of nitre of the last experiment were expanded in the same proportion as in the former, its dilatation, by 116° degrees of heat, should be 0.0679; whereas it was found to be 0.0958. why.

As the dilatation of the spirit of nitre is far greater than that of water by the same degree of heat, and as it consists only of acid and water; it clearly follows, that its superior dilatability must be owing to the acid part: and hence the more acid that is contained in any quantity of spirit of nitre, the greater is its dilatability. We might therefore suppose, that the dilatation of nitre was intermediate betwixt the quantity of water it contains and that of the acid. But there exists another power also which prevents this simple result, viz. the attraction of the acid and water to each other, which makes them occupy less space than the sum of their joint volumes; and by this condensation our author explains his phrase of *accrued density*. Taking this into the account, we may consider the dilatation of the spirit of nitre as equal to those of the quantities of water and acid it contains, minus the condensation they acquire from their mutual attraction; and this rule holds as to all other heterogeneous compounds.

To find the quantities of acid and water in spirit of nitre, whose specific gravity was found in degrees of temperature different from those for which the table was constructed, viz. 54° , 55° , or 56° of Fahrenheit, the surest method is to find how much that spirit of nitre is expanded or condensed by a greater or lesser degree of heat; and then, by the rule of proportion, find what its density would be at 55° . But if this cannot be done, we shall approach pretty near the truth, if we allow $\frac{1}{1000}$ for every 15° degrees of heat above or below 55° of Fahrenheit, when the specific gravity is between 1.400 and 1.500, and $\frac{1}{10000}$ when the specific gravity is between 1.400 and 1.500.—The dilatations of oil and spirit of vitriol were found to be exceedingly irregular, probably by reason of a white foreign matter, which is more or less suspended or dissolved in it, according to its greater or lesser dilution; and

Dilatation
of spirit of
salt by va-
rious de-
grees of
heat.

and this matter our author did not separate, as he intended to try the acid in the state in which it is commonly used. In general he found that 15° of heat caused a difference of above $\frac{1}{1000}$ in its specific gravity, when it exceeds 1.800, and of $\frac{1}{1000}$ when its specific gravity is between 1.400 and 1.300.—The dilatations of spirit of salt are very nearly proportional to the degrees of heat, as appears by the following table.

Degrees of Heat.	Specific Gravity.
33	1.1916
54	1.1860
66	1.1820
128	1.1631

Hence $\frac{6}{1000}$ should be added or subtracted for every 21° above or below 55° , in order to reduce it to 55° , the degree for which its proportion of acid and water was calculated. The dilatability of this acid is much greater than that of water, and even than that of the nitrous acid of the same density.

stances.

429
Mineral al-
kali how
prepared
for these
experi-
ments.

Our author next proceeds to consider the quantity of pure acids taken up at the point of saturation by the various substances they unite with.—He begins with the mineral alkali. Having rendered a quantity of this caustic in the usual manner, and evaporating one ounce of the caustic solution to perfect dryness, he found it to contain 20.25 grains of solid matter. He was assured, that the watery part alone exhaled during evaporation, as the quantity of fixed air contained in it was very small, and to dissipate this a much greater heat would have been requisite than that which he used. This dry alkali was dissolved in twice its weight of water; and saturating it with dilute vitriolic acid, he found it to contain 2.25 grains of fixed air; that being the weight which the saturated solution wanted of being equal to the joint weights of water, alkali, and spirit of vitriol employed.

430
Quantity of
vitriolic
acid neces-
sary to sa-
turate it.

431
Quantity of
ingredients
in Glau-
ber's salt.

The quantity of mere vitriolic acid necessary to saturate 100 grains of pure mineral alkali was found to be 60 or 61 grains; the saturated solution thus formed being evaporated to perfect dryness weighed 36.5 grains; but of this weight only 28.38 were alkali and acid; the remainder, that is, 8.12 grains, therefore, were water. Hence 100 grains of Glauber's salt, perfectly dried, contained 29.12 of mere vitriolic acid, 48.6 of mere alkali, and 22.28 of water. But Glauber's salt crystallized contains a much larger proportion of water; for 100 grains of these crystals heated red hot lost 55 grains of their weight; and this loss Mr Kirwan supposes to arise merely from the evaporation of the watery part, and the remaining 45 contained alkali, water, and acid, in the same proportion as the 100 grains of Glauber's salt perfectly dried above mentioned. Then these 45 contained 13.19 grains of vitriolic acid, 21.87 of fixed alkali, and 9.94 of water: consequently 100 grains of crystallized Glauber's salt contain 13.19 of vitriolic acid, 21.87 of alkali, and 64.94 of water.

432
Quantity of
mineral al-
kali taken
up by de-
phlogistica-
ted nitrous
acid;

On saturating the mineral alkali with dephlogisticated nitrous acid, it was found that 100 grains of the alkali took up 57 of the pure acid in the experiment he most depended upon; though in some others this quantity varied by a few grains: he concludes, therefore, that the quantity of alkali taken up by this acid nearly the same as that taken up by the vitriolic.

lic. Supposing this quantity to be 57 grains, then 100 grains of cubic nitre, perfectly dry, contain 30 of acid, 52.18 of alkali, and 17.82 of water: but cubic nitre crystallized contains something more water; for 100 grains of these crystals lose about four by gentle drying; therefore 100 grains of the crystallized salt contain 28.8 of acid, 50.09 of alkali, and 21.11 of water.

An hundred grains of mineral alkali require from 63 to 66 or 67 grains of pure marine acid to saturate it; but Mr Kirwan supposes that one reason of this variety is, that it is exceeding hard to hit the true point of saturation. Allowing 66 grains to be the quantity required, then 100 grains of perfectly dry common salt contain nearly 35 grains of real acid, 53 of alkali, and 13 of water; but 100 grains of the crystallized salt lose five by evaporation: so that 100 grains of these crystals contain 33.3 of acid, 50 of alkali, and 16.7 of water.

The proportion of fixed air, alkali, and water, was thus investigated: 200 grains of these crystals were dissolved in 240 of water; the solution was saturated by such a quantity of spirit of nitre as contained 40 of pure nitrous acid; whence it was inferred that these 200 grains of salt of soda contained 70 of pure alkaline salt. The saturated solution weighed 40 grains less than the sum of its original weight, and that of the spirit of nitre added to it; consequently it lost 40 grains of fixed air. The remainder of the original weight of the crystals therefore must have been water, viz. 90 grains. Consequently 100 grains of these crystals contained 35 of alkali, 20 of fixed air, and 45 of water. This proportion differs considerably from that assigned by Mr Bergman and Lavoisier, which our author imputes to their having made use of soda recently crystallized; but Mr Kirwan's had been made for some months, and probably lost much water and fixed air by evaporation, which altered the proportion of the whole. According to the calculations of Bergman and Lavoisier, 100 grains of this alkali take up 80 of fixed air. The specific gravity of the crystallized mineral alkali, weighed in ether, was found to be 1.421.

The proportion of the different ingredients in volatile alkalies can only be had from the experiments lately made by Dr Priestley concerning alkaline air. He informs us, that $\frac{1}{100}$ of a measure of this, and one measure of fixed air, saturate one another. Then, supposing the measure to contain 100 cubic inches, 185 cubic inches of alkaline air take up 100 of fixed air; but 185 cubic inches of alkaline air weigh at a medium 42.55 grains, and 100 cubic inches of fixed air weigh 57 grains; therefore 100 grains of pure volatile alkali, free from water, take up 134 of fixed air.

On expelling its aerial acid from a quantity of this volatile alkali in a concrete state, and formed by sublimation, he found, that 53 grains of it were fixed air: according to the preceding calculation, 100 grains of it should contain 39.47 of real alkali, and 7.53 of water, the rest being fixed air.—On saturating a quantity with the vitriolic, nitrous, and marine acids, 100 grains of the mere alkali were found to take up 106 of mere vitriolic acid, 115 of the nitrous, and 130 of the marine acid. The specific gravity of the volatile alkali

alkali weighed in ether (B) was 1.4076. The proportion of water in the different ammoniacal salts could not be found on account of their volatility; but was supposed to be very small, as both volatile alkali and fixed air crystallize without the help of water when in an aerial state.

417
Experiments on
calcareous
earth.

In making experiments on calcareous earth, it was first dissolved in nitrous acid; and after allowing for the loss of fixed air and water, 100 grains of the pure earth was found to take up 104 of nitrous acid; but only 91 or 92 of mere vitriolic acid were required to precipitate it from the nitrous solution.

438
Quantity of marine
acid saturated by
this earth.

Of the marine acid 100 grains of the pure calcareous earth require 112 for their solution. The liquor at first is colourless, but acquires a greenish colour by standing.

439
Proportion of ingredients in
natural
gypsum;

Natural gypsum varies in its proportion of acid, water, and earth; 100 grains of it containing from 32 to 34 of acid and likewise of earth, and from 26 to 32 of water. The artificial gypsum contains 32 of earth, 29.44 of acid, and 38.56 of water. When well dried, it loses about 24 of water; and therefore contains 42 of earth, 39 of acid, and 19 of water, *per* hundred.

440
In nitrous
selenite;

Nitrous selenite (solution of calcareous earth in nitrous acid) carefully dried, contains 33.28 of acid, 32 of earth, and 34.72 of water.

441
In marine
selenite.

The same quantity of marine selenite (solution of calcareous earth in marine acid), well dried, in such a manner as to lose no part of the acid, contain of the latter 42.56, of earth 38, and of water 19.44.

442
Calcined
magnesia
will not
dissolve in
acids with
out heat.

Magnesia, when perfectly dry and free from fixed air, cannot be dissolved in any of the acids without heat. Even the strongest nitrous acid did not act upon it in 24 hours in the temperature of the atmosphere; but in a heat of 180°, the mineral acids, diluted with four, or even six, times their quantity of water, had a very sensible effect upon it: but the quantity of acid dissipated by heat rendered it impossible to ascertain how much was necessary for solution, except by precipitation after it had been dissolved. For this purpose the caustic vegetable alkali was employed; by which it appeared that 100 grains of pure magnesia take up 125 of mere vitriolic acid, 132 of the nitrous, and 140 of the marine. All of these solutions appeared to contain something gelatinous; but none of them reddened vegetable blues; and that in the marine acid became greenish on standing for some time.

443
Proportion of the ingredients in
common
Epsom salt;

An hundred grains of perfectly dry Epsom salt contain 45.67 of mere vitriolic acid, 36.54 of pure earth, and 17.83 of water. Solution of common Epsom salt, however, reddens vegetable blues, and therefore contains an excess of acid. A like quantity of nitrous

444
In nitrous
Epsom

Epsom, well dried, contains 35.64 of acid, 27 of pure earth, and 37.36 of water. The solution of marine Epsom cannot be tolerably dried without losing much of its acid together with the water. The specific gravity of this earth is 2.3296.

445
Cannot be
found in
marine Epsom.

446
Earth of
alum contains a
great quantity of fixed
air.

Most writers on chemistry have said that earth of alum contains scarce any fixed air; but Mr Kirwan

VOL. IV. Part II.

found that it contained no less than 26 *per cent.* though it had been previously kept red-hot for half an hour. It dissolved with a moderate effervescence in acids until the heat was raised to 220°; after which the solution was found to have lost weight in the proportion above mentioned.

Contents,
&c. of the
Salts.

An hundred grains of this earth, deprived of the fixed air, require 133 of the pure vitriolic acid to dissolve them. The solution was made in a very dilute spirit of vitriol, whose specific gravity was 1.093, and in which the proportion of acid to the water was nearly as 1 to 14. It contained a slight excess of acid, turning the vegetable blues to a brownish red; but it crystallized when cold, and the crystals were of the form of alum. Our author, therefore, is of opinion, that this is the true proportion of acid and earth to be used in the formation of that salt, though there was not water enough to form large crystals. Perceiving that the liquor contained an excess of acid, more earth was added; but thus it was found impossible to prevent it from tinging vegetable blues of a red colour until a precipitation was formed: and even when this was the case, though one part of the salt fell in the form just mentioned, yet the rest would still redden vegetable blues as before; though here our author doubts whether this be a mark of acidity. An hundred grains of alum, when dried, contain 42.74 of acid, 32.14 of earth, and 25.02 of water; but crystallized alum loses 44 *per cent.* by defecation: therefore 100 grains of it contain 23.94 of acid, and 58.06 of water. An hundred grains of this

447
Quantity of ingredients in
alum.

448
This salt always contains an excess of acid.

pure earth take up, as near as can be judged, 153 of pure nitrous acid. The solution still reddened vegetable blues; but after the above quantity of earth was added, an insoluble salt began to precipitate. The solution, when cold, became turbid, and could not be rendered quite clear by 500 times its quantity of water. An hundred and seventy-three grains of pure marine acid are required for the dissolution of 100 grains of earth of alum, but the liquor still reddened vegetable blues. After this an insoluble salt was formed; but it is difficult to ascertain the beginning of its formation precisely both in this and the preceding cases. The specific gravity of pure argillaceous earth, containing 25 *per cent.* of fixed air, is 1.9901.

449
Proportion of pure earth of alum taken up by nitrous acid;

450
By marine acid.

In the experiments made by our author on metals, the acids employed were so far dephlogisticated as to be colourless; the metals were for the most part reduced to filings, or to fine powder in a mortar. They were added by little and little to their respective menstrua; much more being thus dissolved than if the whole had been thrown in at once, and the solution was performed in glass vials with bent tubes.

451
Experiments on metals

452
Best method of dissolving them.

An hundred grains of bar-iron, in the temperature of 56°, require for their solution 190 grains of the real acid, whose proportion to that of the water, with which it should be diluted, is as 1 to 8, 10, or 12. It would act on iron, though its proportion were greater or lesser, though not so vigorously; but by applying a heat of 200° towards the end, 123 grains

of real acid would be sufficient. The air produced by this solution is entirely inflammable, and generally amounts to 155 cubic inches.

By the assistance of a strong heat, iron is also soluble in the concentrated vitriolic acid, though in smaller quantity; and instead of inflammable air, a large quantity of vitriolic air is produced, and a little sulphur is sublimed towards the end. The reason of this is, that the concentrated vitriolic acid, containing much less specific fire than the dilute kind, cannot expel the phlogiston in the form of inflammable air (which absorbs a vast quantity of fire), but unites with it when further dephlegmated by heat, and thus forms both vitriolic air and sulphur. An hundred grains of iron dissolved without heat afford more than 400 of vitriol; and 100 grains of vitriol, when crystallized, contain 25 of iron, 20 of real acid, and 55 of water. When calcined nearly to redness, these crystals lose about 40 per cent. of water.

The calces of iron are soluble in the vitriolic acid according to the quantity of phlogiston they contain; the more phlogisticated being more readily soluble, and those which are dephlogisticated less so. The latter not only require more real acid for their solution, but afford only a thick liquor or magma by evaporation, instead of crystals like the others. Hence also solutions of iron, when newly made, diminish, and consequently phlogistificate, the superincumbent air by their gradual emission of phlogiston; at the same time that the calx, becoming more and more dephlogisticated, gradually falls to the bottom, unless more acid be added to keep it in solution.

An hundred grains of iron require for their solution in nitrous acid 142 grains of real acid, so diluted that its proportion to water should be as 1 to 13 or 14; and when this last proportion is used, the heat of a candle may be employed for a few seconds, and the access of common air prevented. Thus about 18 cubic inches of nitrous air are produced, the rest being absorbed by the solution, and no red vapours appear. But if the proportion of acid and water be as 1 to 8 or 10, a much greater quantity of metal will be dephlogisticated by the application of heat, though very little of it be held in solution. Thus, from 100 grains of iron Mr Kirwan has obtained 83.87 cubic inches of nitrous air; and by distilling the solution, a still greater quantity may be obtained which had been absorbed. The reason that nitrous solutions of iron or other metals yield no inflammable air is, because this acid has less affinity to water, and more to phlogiston, than the vitriolic, and likewise contains much less fire than either that or the marine (see n° 278); and therefore unites with phlogiston, instead of barely expelling it. Hence also the vitriolic acid, though united with 30 times its weight of water, will still visibly act on iron, and separate inflammable air in the temperature of 55°; whereas nitrous acid, diluted with 15 times its weight of water, has no perceptible effect on the metal in that temperature. The calces of iron, if not too much dephlogisticated, are also soluble in the nitrous acid.

Two hundred and fifteen grains of real marine acid are required for the solution of 100 grains of iron. When the proportion of water to the acid is as four to one, it effervesces rather too violently with the metal;

and heat is rather prejudicial, as it volatilizes the acid. No marine air flies off; and the quantity of inflammable air is exactly the same as with diluted vitriolic acid. The calces of iron are also soluble in marine acid, and may be distinguished by their reddish colour when precipitated by fixed alkalies, while the precipitates of the metal are greenish.

An hundred and eighty-three grains of real vitriolic acid are required to dissolve an hundred grains of copper; the proportion of acid to that of water being as 1 to 1.5, or at least as 1 to 1.7; and a strong heat must also be applied. Mr Kirwan says he never could dissolve the whole quantity of copper; but to dissolve a given quantity of it, a still greater heat must be employed in the proportion of 28 to 100; but this residuum also is soluble by adding more acid. Copper dephlogisticated in this manner is soluble by adding warm water to the mass.

By treating 128 grains of copper in this manner, we obtain 11 cubic inches of inflammable air and 65 of vitriolic acid air. When inflammable air was obtained, however, our author tells us the acid was a little more aqueous. The reason why copper cannot be dephlogisticated by dilute vitriolic acid, or even by the concentrated kind without the assistance of heat, is its strong attraction to phlogiston, and the great quantity it contains.

An hundred grains of vitriol of copper contain 27 of metal, 30 of acid, and 43 of water; 28 of which last are lost by evaporation or slight calcination. An hundred grains of copper, when dissolved, afford 373 of blue vitriol.

An hundred grains of copper require 130 of pure nitrous acid for their dissolution. If the acid be so far diluted that its proportion of water be as 1 to 14, the assistance of heat will be necessary, but not otherwise. This solution affords 67½ inches of nitrous air.—The calces of copper are soluble in the nitrous acid.

A like quantity of this metal requires 1190 grains of real marine acid, as well as the assistance of a moderate heat, to dissolve them; the proportion of water being as 4½ to 1. By employing a greater heat, more of the acid will be requisite, as much more will be dissipated: the concentrated acid acts more vigorously.—Calces of copper are likewise soluble in the marine acid, though less easily than in the nitrous.

The vitriolic acid dissolves tin but in small quantity; an hundred grains of the metal requiring for their solution 872 of real acid, whose proportion to water should not be less than 1 to 0.9. A strong heat is also required. When the action of the acid has ceased, some hot water should be added to the turbid solution, and the whole again heated. The metal is soluble in a more dilute acid, but not in such quantity.—The solution above mentioned affords 70 cubic inches of inflammable air.—The calces of tin, excepting that precipitated from marine acid by fixed alkalies, are insoluble in the vitriolic acid.

An hundred grains of tin require 1200 of real nitrous acid; whose proportion of water should be at least 25 to 1, and the heat employed not exceeding 60°. The quantity of air afforded by such solution is only 10 cubic inches, and it is not nitrous. The solution

lution is not permanent; for in a few days it deposits a whitish calx, and in warm weather bursts the vial. The calces of tin are insoluble in this acid.

Four hundred and thirteen grains of pure marine acid are required to dissolve 100 grains of tin, the proportion of water being as $4\frac{1}{2}$ to 1. The assistance of a moderate heat is also required. About 90 cubic inches of inflammable, and 10 of marine air, are afforded by the solution; but the calces of tin are nearly insoluble in this acid.

474
Lead with
vitriolic
acid.

An hundred grains of lead require 600 grains of real vitriolic acid for their solution, the proportion being not less than 1 of acid to $\frac{7}{10}$ of water; and it will still be better if the quantity of water be less: for which reason, as in copper, a greater quantity of metal should be employed than what is expected to be dissolved. A strong heat is also requisite; and hot water should be added to the calcined mass, though in small quantity, as it occasions a precipitation.—This metal is also soluble, but very sparingly, in dilute vitriolic acid. Its calces are something more soluble. An hundred grains of vitriol of lead, formed by precipitation, contain 73 of lead, 17 of real acid, and 10 of water.

475
Scarce so-
luble in
dilute vi-
triolic acid.476
With ni-
trous acid.

With spirit of nitre, 78 grains of real acid are required for the solution of 100 of lead, with the assistance of heat towards the end. The proportion of acid to that of water may be about 1 to 11 or 12. This solution produces but eight cubic inches of air, which is nitrous. The calces of the metal are soluble in this acid; but less so when much dephlogisticated. An hundred grains of minium require 81 of real acid. An hundred grains of nitrous salt of lead contain about 60 of the metal.

477
With ma-
rine acid.

Six hundred grains of the real marine acid are required for the solution of 100 grains of lead; the specific gravity of the acid being 1.141, though more would be dissolved by a stronger acid.—The calces of lead are more soluble in this acid than the metal itself. An hundred grains of minium require 327 of real acid; but white lead is much less soluble. The same quantity of plumbum corneum, formed by precipitation, contain 72 of lead, 18 of marine acid, and 10 of water.

478
Silver with
vitriolic
acid.

An hundred grains of silver require 530 of real vitriolic acid to dissolve them; the proportion of acid to water being not less than as 1 to $\frac{8}{10}$; and when such a concentrated acid is used, it acts slightly even in the temperature of 60° ; but a moderate heat is required in order to procure a copious solution. The calces of silver formed by precipitation from the nitrous acid with fixed alkalies are soluble even in dilute vitriolic acid without the assistance of heat. An hundred grains of vitriol of silver, formed by precipitation, contain 74 grains of metal, about 17 of real acid, and 9 of water.

479
With ni-
trous acid.

An hundred grains of the purest silver require for their solution 36 of nitrous acid, diluted with water in the proportion of one part of real acid to six of water, applying heat only when the solution is almost saturated. If the spirit be much more or much less dilute, it will not act without the assistance of heat. The last portions of silver thus taken up afford no air. Standard silver requires about 38 grains of real acid to dissolve the same proportion of it; and the solution affords 20 cubic inches of nitrous air; whereas 100 grains of silver revived from luna cornea afford about 14.

Mr Kirwan has never been able to dissolve silver in the marine acid, though Mr Bayen says he effected the dissolution of three grains and a half of it by digestion for some days with two ounces of strong spirit of salt. Newmann informs us also, that leaf-silver is corroded by the concentrated marine acid. It is dissolved, however, by the dephlogisticated spirit of salt, as well as by the phlogisticated acid when reduced to a state of vapour. An hundred grains of luna cornea contain 75 of silver, 18 of acid, and 7 of water.

Mr Kirwan found that kind of aqua regia to succeed best in the dissolution of gold, which was prepared by mixing together three parts of the real marine acid with one of the nitrous acid. Both of them ought also to be as concentrated as possible; though, when this is the case, it is almost impossible to prevent a great quantity from escaping, as a violent effervescence takes place for some time after the mixture. Aqua regia made with common salt or sal ammoniac and spirit of nitre, is much less aqueous than that proceeding from an immediate combination of both acids; and hence it is the fittest for producing crystals of gold. Very little air is produced by the solution of this metal, and the operation goes on very slow. It is, however, better promoted by allowing it sufficient time, than by applying heat. An hundred grains of gold require for their solution 246 grains of real acid, the two acids being in the proportion above mentioned. Though soluble in the dephlogisticated marine acid, it is only in very small quantity, unless the acid be in a state of vapour; for in its liquid state it is too aqueous. In vitriolic and nitrous acids it is insoluble, tho' the calces are somewhat soluble in the nitrous, more easily in the marine, but scarcely at all in the vitriolic acid. Mr Kirwan says, that gold in its metallic state may be diffused through the concentrated nitrous acid, tho' not dissolved in it; contrary to the opinion of other chemists, who have affirmed that a true dissolution takes place.

An hundred grains of mercury require for their solution 230 grains of real vitriolic acid, whose proportion to that of water is as 1 to $\frac{8}{10}$. A strong heat is also requisite, and the air produced is vitriolic. Precipitate *per se* is still less soluble.—An hundred grains of vitriol of mercury, produced by precipitation, contain 77 of metal, 19 of acid, and 4 of water.

In spirit of nitre, 100 grains of mercury are dissolved by 28 of real acid, whose proportion to the water it contains is as 1 to $1\frac{5}{10}$. In this acid the solution takes place without heat; but it may also be dissolved in a much more dilute acid, provided heat be applied. About 12 cubic inches of air are produced when heat is not applied; but M. Lavoisier found the produce much greater. This, says Mr Kirwan, was evidently caused by his using red or yellow spirit of nitre, which already contains much phlogiston. Precipitate *per se* is much less easily dissolved in the nitrous acid, which Mr Kirwan supposes to be owing to the attraction of the aerial acid.

The marine acid, in its common phlogisticated state, does not act on mercury, at least in its usual state of concentration; though M. Homberg, in the Paris Memoirs for the year 1700, affirms, that he dissolved it by several months digestion in this acid. When dephlogisticated, it certainly acts upon it, though very weakly.

weakly while in a liquid state. Precipitate *per se* is also soluble in the marine acid with the assistance of heat. An hundred grains of corrosive sublimate contain 77 of mercury, 16 of real acid, and six of water. The like quantity of mercurius dulcis contains 86 of metal and 14 of acid and water.

Zinc requires for its solution an equal quantity of real vitriolic acid, whose proportion to that of water may be as 1 to 8, 10, or 12. Heat must be applied towards the end, when the saturation is almost completed. By the help of heat also this semimetal is soluble in the concentrated vitriolic acid, but a small quantity of black powder remains in all cases undissolved. An hundred cubic inches of inflammable air are produced. An hundred grains of vitriol of zinc contain 20 of zinc, 22 of acid, and 58 of water. The calces of zinc, if not exceedingly dephlogisticated, are also soluble in this acid.

An hundred and twenty-five grains of real nitrous acid, whose proportion to water is that of 1 to 12, are required for the solution of 100 grains of this semimetal, applying heat slightly from time to time. A concentrated acid dissolves less of the metal, as a great quantity of the menstruum escapes during the effervescence. No nitrous air can be procured, the acid being partly decomposed during the operation. The calces of zinc, if not too much dephlogisticated, are likewise dissolved by the nitrous acid.

An hundred grains of zinc require for their dissolution 210 grains of real marine acid, the proportion of it to the water being as 1 to 9. If a more concentrated spirit of salt be made use of, a considerable part of it will be dissipated during the effervescence, and consequently more will be required for the solution. The calces of zinc are also soluble in the marine acid.

Only three grains of bismuth were dissolved by 200 of oil of vitriol, whose specific gravity was 1.863, though a strong heat was used at the same time. A greater quantity was indeed slightly dephlogisticated; but when the gravity of the acid was reduced to 1.200, only a single grain of the metal was dissolved by 400 of it. The calces of this semimetal are much more soluble. Four cubic inches of vitriolic air were afforded by the solution of three grains of bismuth.

In spirit of nitre, 100 grains of real acid are only required to dissolve 100 grains of the metal. The proportion of water to the acid ought to be as 8 or 9 to 1; in which case a gentle heat may be applied. The solution affords 44 cubic inches of nitrous air. The calces of bismuth are also soluble in this acid.—Only three or four grains of it were dissolved by 400 of marine acid, whose specific gravity was 1.220.

About four grains of nickel were dissolved in an hundred of the concentrated vitriolic acid with the assistance of a strong heat; but its calces are much more soluble.—An hundred grains of nickel require for their solution 112 of real nitrous acid, whose proportion to water is as 1 to 11 or 12. The product of nitrous air is 79 inches. The calces are also soluble. A moderate heat is necessary for the dissolution of the metal; but a concentrated acid acts so rapidly, that much of it is dissipated.—Only four or five grains of nickel are dissolved by 200 of spirit of salt whose specific gravity was 1.220. An acid of this degree of strength acts without the assistance of heat, though

a weaker acid requires it, and dissolves still less of the metal. The calces of nickel are also soluble with difficulty in this acid.

Four hundred and fifty grains of real vitriolic acid, whose proportion to water is not less than 1 to 15, are required for the dissolution of 100 grains of cobalt, assisted by a heat of 270° at least. A solution is obtained by pouring warm water on the dephlogisticated mass.—The calces of cobalt, however, are more soluble; so that even a dilute acid will serve.—In spirit of nitre, the like quantity of cobalt requires 220 grains of real acid, whose proportion to water is as 1 to 4; giving a heat of 180° towards the end.—The calces of the metal are soluble in the nitrous acid.—An hundred grains of spirit of salt, whose specific gravity is 1.178, dissolves, with the assistance of heat, two grains and a half of cobalt; and a greater quantity will be dissolved by an acid more highly concentrated.—The calces of cobalt are more soluble.

An hundred grains of regulus of antimony require for their solution 725 grains of real vitriolic acid, whose proportion to water is as 1 to 75, assisted by a heat of 400°. A large quantity of regulus should be put into the acid; and the resulting salt requires much water to dissolve it, as the concentrated acid lets fall much when water is added to it. A less concentrated acid will likewise dissolve this semimetal, but in smaller quantity. The calces of antimony, even diaphoretic antimony, are somewhat more soluble. Nine hundred grains of real nitrous acid are required for the solution of 100 grains of regulus; the proportion of acid to the water of the solvent being as 1 to 12, and assisted by an heat of 110°; but the solution becomes turbid in a few days. The calces are much less soluble in this acid.—Only one grain of the regulus is dissolved by 100 of spirit of salt, whose specific gravity was 1.220, with the assistance of a slight heat; and that which is only 1.178 dissolves still less; but Mr Kirwan is of opinion that the concentrated acid would, in a long time, and by the assistance of a gentle heat, dissolve much more. The calces dissolve more easily in the marine acid.

Eighteen grains of regulus of arsenic are dissolved in a heat of 250° by 200 grains of real vitriolic acid, whose specific gravity is 1.871. About seven of these parts crystallize on cooling, and are soluble in a large quantity of water. The calces of arsenic are more soluble in this acid.—An hundred and forty grains of real nitrous acid are requisite for the solution of 100 grains of regulus of arsenic; the proportion of acid to the water being as 1 to 11. The solution affords 102 cubic inches of nitrous air, the barometer being at 30 and the thermometer at 60. Calces of arsenic are likewise soluble in this acid.

An hundred grains of spirit of salt, whose specific gravity is 1.220, dissolve a grain and an half of regulus of arsenic; but the marine acid, in its common state, that is, when its gravity is under 1.17, does not at all affect it. The arsenical calces are less soluble in this than in the vitriolic or nitrous acids.

§ 3. Of the Quantity of Phlogiston contained in different Substances.

Having gone through all the various bases with which acids are usually combined, and ascertained the quantity

quantity of different ingredients contained in the compounds resulting from their union, we ought next to give an account of our author's experiments on phlogiston; but as his sentiments on that subject are taken notice of elsewhere, we shall content ourselves with briefly mentioning the very ingenious methods by which he discovers the quantities of it contained in various kinds of air and in sulphur.

505
Quantity
of phlo-
giston con-
tained in ni-
trous air.

Having proved that inflammable air, in its concrete state, and phlogiston are the same thing, Mr Kirwan proceeds to estimate the quantity contained in nitrous air in the following manner.

"An hundred grains of filings of iron, dissolved in a sufficient quantity of very dilute vitriolic acid, produced, with the assistance of heat gradually applied, 155 cubic inches of inflammable air; the barometer being at 29.5, and the thermometer between 50° and 60°. Now, inflammable air and phlogiston being the same thing, this quantity of inflammable air amounts to 5.42 grains of phlogiston.—Again, 100 grains of iron dissolved in dephlogisticated nitrous acid, in a heat gradually applied and raised to the utmost, afford 83.87 cubic inches of nitrous air. But as this nitrous air contains nearly the whole quantity of phlogiston which iron will part with (it being more completely dephlogisticated by this than any other means), it follows, that 83.87 cubic inches of nitrous air contain at least 5.42 grains of phlogiston. But it may reasonably be thought, that the whole quantity of phlogiston which iron will part with is not expelled by the vitriolic acid, but that nitrous acid may expel and take up more of it. To try whether this was really the case, a quantity of green vitriol was calcined until its basis became quite insipid; after which, two cubic inches of nitrous air were extracted from 64 grains of this ochre; and consequently 100 grains would yield 3.12 cubic inches of nitrous air. If 83.87 cubic inches of nitrous air contain 5.42 of phlogiston; then 3.12 cubic inches of this air contain 0.2 of phlogiston. The nitrous acid, therefore, extracts from 100 grains of iron two-tenths of a grain more phlogiston than vitriolic acid does. Therefore 83.87 cubic inches of nitrous air, containing nearly the whole phlogiston of the iron, have 5.62 of this substance. Hence 100 cubic inches of nitrous air contain 6.7 grains of phlogiston."

2d 505
Quantity
of phlogis-
ton in fixed
air;

With regard to the quantity of phlogiston in fixed air, after proving at length that it is composed of dephlogisticated air united to the principle of inflammability, Mr Kirwan ascertains the quantity of the latter in the following manner: "Dr Priestley, in the fourth volume of his Observations, p. 380, has satisfactorily proved, that nitrous air parts with as much phlogiston to common air, as an equal bulk of inflammable does when fixed in the same proportion of common air. Now, when inflammable air unites with common air, its whole weight unites to it, as it contains nothing else but pure phlogiston. Since, therefore, nitrous air phlogisticates common air to the same degree that inflammable air does, it must part with a quantity of phlogiston, equal to the weight of a volume of inflammable air, similar to that of nitrous air. But 100 cubic inches of inflammable air weigh three grains and a half; therefore 100 cubic inches of nitrous air part with 3.5 grains of phlogiston, when they communicate their phlogiston to as much common

air as will take it up. In this process, however, the nitrous air does not part with the whole of the phlogiston it contains, as appears by the red colour it constantly assumes when mixed with common or dephlogisticated air; which colour belongs to the nitrous acid, combined with the remainder of its phlogiston, whence the acid produced is always volatile.

"One measure of the purest dephlogisticated air and two of nitrous air occupy but $\frac{3}{5}$ of one measure, as Dr Priestley has observed. Suppose one measure to contain 100 cubic inches, then the whole, very nearly, of the nitrous air will disappear (its acid uniting to the water over which the mixture is made), and 97 cubic inches of the dephlogisticated air, which is converted into fixed air by its union with the phlogiston of the nitrous air; therefore 97 cubic inches of dephlogisticated air take up all the phlogiston which 200 cubic inches of nitrous air will part with; and this we have found to be seven grains: therefore a weight of fixed air equal to that of 97 cubic inches of dephlogisticated air, and 7 of phlogiston, will contain seven grains of the latter. Now, 97 cubic inches of dephlogisticated air weigh 40.74 grains; to which adding 7, we have the whole weight of the fixed air, = 47.74 grains, = 83.755 cubic inches; and consequently 100 cubic inches of fixed air contain 8.357 grains of phlogiston, the remainder being dephlogisticated air. An hundred grains of fixed air therefore, contain 14.661 of phlogiston, and 85.339 of elementary or dephlogisticated air. Hence also 100 cubic inches of dephlogisticated air are converted into fixed air by 7.2165 grains of phlogiston, and will be then reduced to the bulk of 86.34 cubic inches.

To find the quantity of phlogiston in vitriolic acid air, our author pursued the following method.

506
In vitriolic
acid air.

1. He found the quantity of nitrous air afforded by a given weight of copper, when dissolved in the dephlogisticated nitrous acid, and by that means how much phlogiston it parts with.

2. He found the quantity of copper which a given quantity of the dephlogisticated vitriolic acid could dissolve; and observed, that it could not entirely saturate itself with copper without dephlogisticating a further quantity which it does not dissolve.

3. He found how much it dephlogisticates what it thoroughly dissolves, and how much it dephlogisticates what it barely calcines.

4. How much inflammable air a given quantity of copper affords when dissolved in the vitriolic acid to the greatest advantage.

5. He deducts from the whole quantity of phlogiston expelled by the vitriolic acid the quantity of it contained in the inflammable air; the remainder shows the quantity of it contained in the vitriolic acid air.

The conclusion deduced from experiments conducted after this manner is, that 100 cubic inches of vitriolic air contain 6.6 grains of phlogiston, and 71.2 grains of acid; and 100 cubic inches of this air weighing 77.8 grains, 100 of it must contain 8.48 grains phlogiston, and 91.52 of acid.

To find the quantity of phlogiston in sulphur, Mr Kirwan proposed to estimate that of the fixed air produced during its combustion. For this purpose he firmly tied and cemented to the open top of a glass-bell a large bladder, destined to receive the air expanded by combustion, which generally escapes when this

507

Quantity of
Phlogiston
in different
Substances

508
Proper method of
burning sulphur.

this precaution is not used. Under this bell, containing about 3000 cubic inches of air, a candle of sulphur, weighing 347 grains, was placed; its wick, which was not consumed, weighing half a grain. It was supported by a very thin concave plate of tin, to prevent the sulphur from running over during the combustion; and both were supported by an iron wire fixed in a shelf in a tub of water. As soon as the sulphur began to burn with a feeble flame, it was covered with the bell, the air being squeezed out of the bladder. The inside of the bell was soon filled with white fumes, so that the flame could not be seen; but in about an hour after all the fumes were thoroughly subsided, and the glass become cold, as much water entered the bell as was equal to 87.2 cubic inches; which space our author concludes to have been occupied by fixed air, and which must have contained 7.287 grains of phlogiston. The candle of sulphur being weighed was found to have lost 20.75 grains; therefore 20.75 grains of sulphur contain 7.287 of phlogiston, besides the quantity of phlogiston which remained in the vitriolic air. This air must have amounted to 20.75— $7.287 = 13.463$ grains, which, as already shown, contain 1.41 grains of phlogiston. Therefore the whole quantity of phlogiston in 20.75 grains of sulphur is 8.428; of consequence 100 grains of sulphur contain 59.39 of vitriolic acid, and 40.61 of phlogiston.

509
Quantity of phlogiston in marine acid air.

The quantity of phlogiston contained in marine acid air was found by the following method.—Eight grains of copper dissolved in colourless spirit of salt afforded but 4.9 inches of inflammable air; but when the experiment was repeated over mercury, 91.28 cubic inches of air were obtained. Of these only 4.9 cubic inches were inflammable; and consequently the remainder, 86.38 inches, were marine air, weighing 56.49 grains.—Now, as spirit of salt certainly does not dephlogistate copper more than the vitriolic acid does, it follows, that these 4.9 cubic inches of inflammable air, and 86.38 of marine air, do not contain more phlogiston than would be separated from the same quantity of copper by the vitriolic acid; and since 100 grains of copper would yield to the vitriolic acid 4.32 grains of phlogiston, 8.5 grains of copper would yield 0.367 grains of phlogiston. This therefore is the whole quantity extracted by the marine acid, and contained in 91.28 cubic inches of air; and, deducting from this the quantity of phlogiston contained in 4.9 cubic inches of inflammable air $= 0.171$ grains, the remainder, *viz.* $0.367 - 0.171 = 0.196$, is all the phlogiston that can be found in 86.38 cubic inches of marine air. Then 100 cubic inches of it contain but 0.227 of a grain of phlogiston, 65.173 grains being acid.—Hence we see why it acts so feebly on oils, spirit of wine, &c. and why it is not dislodged from any basis by uniting with phlogiston, as the vitriolic and nitrous acids are, its affinity to it being inconsiderable.

510
Why marine acid acts so weakly.

§ 4. *Remarks on the Doctrines of the Quantity and Specific Gravity above delivered.*

2d 510
Mr Keir's objections to Kirwan's doctrines.

To this doctrine of the specific gravity and quantity of acid contained in different substances, Mr Keir has made several objections. 1. Mr Kirwan supposes, that marine acid gas is the pure and solid marine acid divested of all water and other matter. Its apparent dryness in this respect, however, is no argument that

it really contains no water; for water itself, reduced to a state of vapour, possesses no moistening property. There is great reason to believe that water is a constituent part of some gases, and it is certain that all of them are capable of holding it in solution. As moist materials, therefore, are employed in the preparation of marine acid air, there seems no reason to believe, that in any way in which Mr Kirwan could obtain it, there was reason to suppose it perfectly free of water; in which case the density of the acid would be greater, and its quantity smaller than he supposes.

2. A considerable part of the density of the acid absorbed in the experiment, probably arose from the condensation which always accompanies the union of a concentrated acid with water. Mr Kirwan allows this to be the case with the nitrous and vitriolic acids, but thinks it too inconsiderable to deserve notice in the marine. His reasoning, however, does not appear satisfactory, or his experiments on the subject conclusive. He observes, that the length of time taken up in effecting an union between the marine gas and water, is no argument against their attracting one another strongly when once united; and it is certain that part of this acid gas is very quickly absorbed by water. He also finds fault with his accuracy in calculation; and asserts, that if matters are fairly stated, the real density of the marine acid gas will be considerably less than Mr Kirwan makes it.

3. A great obstacle even to an approximation towards the real density of the acid, arises from the condensation which the water, as well as the acids, must suffer in the process: and in this case, where a general condensation takes place, he asks, "How shall we determine the part of the condensation that belongs to the water, and the part that the acid sustains?" This, with other considerations, makes Mr Keir "doubt of the possibility of solving the question concerning the actual density of pure and solid acids." The investigation of the question, indeed, he does not consider as a matter of great consequence, as every useful application may be obtained, by first investigating the comparative strengths of different portions of the same acid rendered more or less dilute; and then by finding out the strength of the vitriolic, nitrous, and marine acids of known densities, so that they may be compared together. "Homberg (says he) has the merit of making the first essay towards this investigation. Bergman and Wenzel have supplied the defect of Homberg, by taking into consideration the gas united with alkaline substances; and Mr Kirwan, by using determinate quantities of acid liquors of known densities, has considerably improved the method of Bergman: and whoever succeeds these able chemists in this inquiry, may avail himself greatly of their labours, particularly those of Mr Kirwan." He concludes with stating the results of the inquiries made by the chemists above mentioned; on which he makes the following remarks.

"The discordancy of these results is very striking, and gives but an humiliating representation of the precision of our present knowledge in chemistry. A great part of the difference arises undoubtedly from the different views in which these authors considered the dryness or purity of the acids. Mr Kirwan, as we have seen, endeavoured to find their density and quantity in

Remarks on the former Doctrines.

3d 510
Great differences in the calculations of different authors.

Remarks
on the former
Doctrines.

a state of perfect dryness and purity; which he supposed to exist in the marine acid gas: with which he compared and inferred the densities and quantities of the nitrous and vitriolic acids, upon the supposition that equal quantities of these several acids are saturated by a given weight of fixed alkali. Besides the uncertainty of his principles, from which he deduces the density and quantity of the marine acid, his applications from thence to deduce the densities of the pure nitrous and vitriolic acids, being founded on the above supposition, must partake of its defects. The alkali which he happened to fix on as the standard by which he compared the strengths of the different acid liquors, in order to determine the quantity of real acid they contained, and thence to determine their density in a solid state, was the fixed vegetable. Having found that 100 grains of his real marine acid could saturate 215 grains of this alkali, he infers, that the same proportion is applicable to the other acids: and accordingly we find that 100 grains of each of the pure and real mineral acids are saturated by an equal quantity, viz. 215 grains of this alkali. But if we examine the other columns of his table, we shall at once see, that, in other substances soluble by acids, this equality does not exist; and that every such substance has a ratio peculiar to itself, with respect to the proportions of these acids necessary for its saturation. It is evident, therefore, that if Mr Kirwan had fixed on the mineral alkali, the volatile alkali, lime, or any other substance, as a standard, instead of vegetable alkali, his determination of the densities of the real vitriolic and nitrous acids would have been different; and as no reason can be assigned why the vegetable alkali or any other substance should have the prerogative over the rest, it is obvious that there can be no such general standard, but that each substance possesses solely the capacity of determining the proportions of the several acids necessary for its saturation.

"The other chemists were contented to consider as the pure and dry acid, that which actually remains in the neutral salt, after this has been rendered as dry as possible by exposure to a red heat: and having made their alkalies as dry as they could, they supposed these alkalies to retain the same weight in the dried neutral salt; and that the augmentation of the weight gained by the alkali during the formation of the neutral salt showed the weight of the dry acid. The uncertainty which affects this method arises from the different capacities which different neutral salts may possess of retaining more or less water, either as a constituent part of the dry salt, or merely by the strength of adhesion or affinity. Nevertheless, this method being founded solely on experiment, without any theoretical inductions, seems to furnish some approximation, not perhaps of the absolute quantity of the acids in their driest possible state, but of the acids as they actually exist in these salts comparatively with each other. Though the disagreements between Bergman's and Wenzel's results are little in comparison of the difference between them and Kirwan's, yet as their experiments were made nearly in the same manner, and upon the same grounds, there seems to be sufficient reason to wish for a careful repetition of their experiments, or of others with the same view, and less liable to objections.

"The only difference in the methods employed by these two celebrated chemists consisted in the mode of saturation. Bergman probably used the common method, but Wenzel employed a very peculiar one. He added to his alkali a greater quantity of acid than was necessary for the saturation; and after the alkali was dissolved, he added a lump of zinc, or of oyster-shell, in order to saturate completely the superfluous acid. By observing how much of the zinc or oyster-shell the acid dissolved, and knowing how much of these substances was soluble in his acid by former experiments, he inferred the quantity of acid left for the saturation of the alkali. Having thus ascertained the quantity necessary to saturate the alkali, he mixed together the proper proportions of these, and formed his neutral salt by evaporating the mixture and drying the salt with a red heat. Perhaps the difference in the results obtained by these two chemists might arise from their different modes of saturation. The common method of ascertaining the point of saturation by means of litmus or other blue vegetable juices, appears sufficiently exact, is simpler, and therefore preferable to that used by Wenzel.

"The standard for comparing the strengths of acids, and likewise of alkalies with one another, may be either an acid or an alkaline substance; and if we had one of each, the proportion of whose quantities requisite for their mutual saturation were well ascertained, the conveniency in making the experiments would be obvious, and the certainty greater. Alkaline, and the earthy substances that are soluble in acids, are seldom pure enough for this purpose. They generally contain quantities, which are not constant, of fixed air, siliceous earth, magnesia, neutral salts, and inflammable matter, which render any of those that are commonly met with unfit for the purpose without a very skilful and careful purification. The chemists who have made experiments to determine the proportions of acids and alkalies requisite for each other's saturation, have scarcely been explicit enough in explaining the means of purifying the alkalies which they employed; for those in commerce are quite uncertain in strength and purity: and as to the general rules for making allowances for any heterogeneous substances they may contain, they are quite inapplicable to delicate experiments. No other method seems proper for ascertaining the purity of alkalies but that of crystallization; of which both the vegetable and mineral alkalies are susceptible, especially the latter, which on account of its being more easily reducible into crystals, is therefore preferable. These alkaline crystals, however, are not fit to be used as a standard, because they either are apt to be insufficiently dried, or, upon exposure to air, to lose a part of the water of their crystallization, and to fall into powder. Even if they should be taken, as is possible with due care, at the exact state of dry but entire crystals, another uncertainty arises from a property which seems to be common to them all, namely, that of retaining a greater or smaller quantity of water, according to the degree of heat in which they were crystallized; the colder the weather the greater quantity of water entering into the composition of the crystals. It seems possible, however, to make a pretty accurate standard of mineral alkali in the following manner: Let the alkali be purified by repeated solu-

tion and crystallization, using only such as are formed first, and rejecting the remaining liquors. Let the pure crystals be exposed to a dry air until they have completely effloresced or fallen into a dry white powder; which alteration may be facilitated by bruising the crystals, and changing the surface of the powder. Let this powder be then exposed for a certain and determinate time to a constant heat, as that of boiling water for 12 hours; letting the surface exposed be in some given proportion, suppose of a square inch to an ounce of the powder of crystals, and let it be stirred every two hours. When thus dried, let them be put while hot into a bottle, and well stopped. This powder I have found to be an uniform and constant standard for ascertaining the strength of acids; and also, by comparison by means of acids, of other alkaline substances."

With regard to an acid standard, our author recommends oil of vitriol; which, he says, as it comes from the hands of the British manufacturers, is of the specific gravity of about 1.846, but soon becomes weaker, unless carefully kept from the external air; and in general he rates it at 1.844. One part of this acid mixed with nine of water, is of a very convenient strength for use; and as every ten grains of the mixture contain one of the standard acid, the computations are thus rendered easy: and by these standards, the strength of all acids, alkalies, and substances soluble in acids, may be measured and compared together.

5th 510
His method
of finding
the specific
gravity of
different
liquors.

To determine the specific gravity of liquors with accuracy, our author recommends the method of weighing them in a phial fitted with a glass-stopper, which can only enter a certain length into the neck. In this way, he observes, no other inconvenience can ensue than the slight one, that the glass-stopper, by very frequent use, is apt to wear itself and the neck of the phial also; so that after a great number of experiments, it will at last diminish, in some measure, the capacity of the phial itself. This, however, is but very trifling, and may be corrected at any time. Mr Keir has besides found, that after some hundreds of experiments, the error amounted only to one quarter of a grain in 101 grains.

"The methods hitherto practised (says he) for ascertaining the quantities of acids and alkalies contained in neutral salts, seem to be liable to several objections besides those above mentioned, arising from the different proportions of water remaining in a neutral salt, after exposure to a red heat, which heat is also very indefinite. In boiling the saturated mixture of acid and alkali to dryness, and afterwards in exposing this salt to a red heat, it has been supposed that nothing but water is expelled; and some chemists, who have given the results, have also determined the weight of the alkali which enters into the neutral mixture, by evaporating to dryness an equal quantity of the alkaline solution which had been employed in the saturation, and weighing the dry solution, on the supposition that nothing is expelled but water. It is certain, however, that in the evaporation both of alkalies and neutral salts, a considerable portion of the saline matter is elevated towards the end, when the liquor becomes concentrated and acquires a degree of heat considerably above that of boiling water. The fol-

Nº 71.

lowing method appears best for determining the relative quantities of acid and alkali, or other substance existing in neutral salts.

"To a given number of grains, suppose 100 of the standard vitriolic acid, or to a proportionable quantity of any other acid, add as much of the alkali or other soluble substance as is requisite for the saturation, and note the quantity required, which suppose to be 150 grains. We have thus a solution of the neutral salt, which is the object of the experiment; the quantities of acid and basis contained in which are known, and the general proportion of the quantity of the acid to its basis in the neutral salt determined, viz. as 100 to 150. The next thing to be discovered is the weight of the dry neutral salt contained in this solution, in order to know the proportion of the dry neutral salt to its acid and basis. For this purpose, let a given quantity of the same neutral salt, either in the state of crystals or dried to any given degree, be dissolved in water. Let this solution be brought to the same density as the former, by adding water to the heavier of the two: then, by knowing the weight of each solution, and the quantity of dry neutral salt which was actually dissolved in one of them, the quantity contained in the other may be deduced; and thence the quantities of standard acid, or of other acid proportioned to it, and of the alkali employed, or other soluble substance contained in a given quantity of the neutral salt, are determined; also the quantity of water contained in the neutral salt, that is greater or less than what is contained in the quantity of acid employed, will be known, over and above any water that may have been contained in the alkali or other basis of the neutral salt; the quantity of which water, if any, cannot be determined.

"By this method may be ascertained the proportion of the acid, of the basis, and of the neutral salt, to each other; not indeed the quantity of acid and of alkali deprived of all water, but the quantity of acid, equal in intensity of acidity to a known portion of the standard acid; and also the quantity of such alkali or other soluble substance as was employed; the relative strength of which is known from its ratio to the standard acid."

The translator of Wiegand's System of Chemistry totally disagrees with Mr Kirwan's calculation of the quantity of phlogiston contained in sulphur; but as his objection seems to arise rather from an inclination to the antiphlogistic doctrine than a real discussion of the subject, this can have but little weight. It is possible indeed that Mr Kirwan may have over-rated the quantity of phlogiston this substance contains, which is indeed larger than that allowed by other chemists. "Brandt (says the translator), who has been most generally followed, reckons it only at $\frac{1}{8}$; and it has always appeared to me, that the weight of phlogiston in sulphur is almost infinitely small." His objection proceeds on a maxim which he thinks he has demonstrated, viz. that sulphur is composed, not of the vitriolic acid and phlogiston, but of the base of vitriolic acid and phlogiston. No experiments hitherto made, however, have been able to show this base distinct from the acid; nor have we any reason to suppose that the increase of weight in the vitriolic acid above the sulphur

from

Earth. from which it is produced, arises from any thing besides the accession of mere water, which the air parts with during the combustion. Hence, if the sulphur is burnt in a very moist air, the quantity of acid obtained will be four or five times the weight of the sulphur.

SECT. IV. *Earths.*

THESE are divided into five classes: 1. Absorbent, alkaline, or calcareous earths: 2. Argillaceous earths or clay: 3. The flinty: 4. The fusible earths: and, 5. The talks.

1. The first class comprehends all those that are capable of being converted into lime. They are found of various degrees of hardness; but none of them are capable of totally resisting the edge of a knife, or striking fire with steel. They are found to consist of a very friable earth, joined with a large quantity of air and some water. They effervesce with an acid when poured on them; by which they are distinguished from all other kinds of earth, except the argillaceous. When calcined by a strong fire, they part with the water and air which they contained, and then acquire a great degree of causticity, lose their power of effervescing with acids, and become what is a *quicklime*. They are soluble in acids, but not equally so in all. The vitriolic and tartareous acids form compounds with them very difficultly soluble; the *selenites*, formed by the vitriolic acid and calcareous earth, requiring, according to Mr Beaumé, an ounce of water to dissolve a single grain of it. The solubility of the tartareous selenite hath not yet been determined.—With the other mineral acids, the calcareous earths become easily soluble; and by proper management form concretes which appear luminous in the dark, and are called *phosphori*.

511
Quicklime.

512
Argillaceous.

2. The argillaceous earths differ from the calcareous, in not being convertible into quicklime. When mixed into a paste with water, and exposed to the fire, they shrink remarkably, crack in many places, and become excessively hard. By being gently dried in the open air before they are turned, they do not crack, and thus may be formed into vessels of any shape. Of this kind of earth are formed all the brown sort of earthen ware. The purest kind of argillaceous earth naturally found, is that whereof tobacco-pipes are made.

All the argillaceous earths are soluble in acids. With the vitriolic they dissolve into a gelatinous tough liquor very difficultly crystallizable; but which, on the addition of some fixed or volatile alkali, may be shot into crystals of the salt called *alum*. With the other acids they form astringent salts of a similar nature.

The attraction between the argillaceous earths and acids is very weak, yielding not only to alkaline salts both fixed and volatile, but even to some metals, particularly iron; but these earths have as yet been but little the subject of chemical examination in this way. They have a remarkable property of absorbing the colouring matter of cochineal, Brasil-wood, &c. as have also the calces of some metals.

Both the calcareous and argillaceous, and indeed all earths when pure, resist the utmost violence of fire; but when mixed together will readily melt, especially if in contact with the burning fuel. Dr Lewis having

VOL. IV. Part II.

made covers to some crucibles of clay and chalk mixed together, found that they melted into a yellow glass, before the mixtures in the crucibles were fused in the least. But though they melted thus readily when in contact with the fuel, it was with great difficulty he could bring them to a transparent glass when put into a crucible.

The other species of earths, viz. the flinty, fusible, and talky, being no other way the subjects of chemistry than as they are subservient to the making of glass, all that can be said of them will most properly come under that article. For their different species, see MINERALOGY.

Besides the above mentioned species of earths, there are others which may be called *anomalous*, as having some resemblance of the calcareous and argillaceous, and yet being essentially different from them. These are the white earth called *magnesia alba*, the earth of burnt vegetables, and that produced from burning animal substances.

Magnesia alba was at first prepared from the thick liquor remaining after the crystallization of nitre; and is now found to be contained in the liquor called *bittern*, which is left after the separation of common salt from sea-water. In the former case it was united with the nitrous, in the latter with the vitriolic acid. It is also found naturally in the soft kind of stone called *steatites* or "soap stone;" and in the concrete used for taking spots out of cloaths, called *French chalk*. It differs from the calcareous earths, in not acquiring any causticity when deprived of its air, of which it contains so large a quantity as to lose two-thirds of its weight when calcined. From the argillaceous it differs in not burning hard when mixed with water, nor forming a tough ductile paste. It is easily soluble in all the acids, even the vitriolic; with which it forms the bitter purging salt commonly called *Epsom salt*, from its being first discovered in the waters of Epsom. With all the other acids it likewise forms purgative compounds, which are either very difficultly or not at all crystallizable.—Like other pure earths, it cannot be melted by itself; but, on proper additions, runs into a beautiful green glass.

The earth of burnt vegetables is thought by Dr Lewis to be the same with magnesia alba; but on trying the common wood ashes, they were found to be very different. This kind of earth is fusible, by reason of the alkaline salts contained in it. Animal earth is both very difficult of solution in acids, and impossible to be melted in the strongest fire. It dissolves, however, in acid liquors, though slowly; but the nature of the compounds formed by such an union are as yet unknown. The softer parts of animals, such as blood, flesh, &c. are said to yield a more soluble earth than the others. Animal earth has lately been supposed to be compounded of calcareous earth and phosphoric acid; but this opinion is shown to be erroneous under the article BONES. The phosphoric acid produced from these, is with reason supposed to be only the vitriolic acid changed.

SECT. V. *Inflammable Substances.*

THESE comprehend all vegetable, animal, and some mineral substances. They are distinguished from all others,

Phenomena
on burning.

others, by emitting a gross thick smoke and flame, when a certain degree of heat is applied. To this, however, spirit of wine and all preparations from it are exceptions. They burn without the least smoke; and if a glass bell is held over the burning spirit, no foot is formed, only a quantity of water is found condensed on its sides. Even the grosser oils, if slowly burnt with a very small flame, will yield no foot; and an exceeding great quantity of water, fully equal in weight and bulk to the oil employed, may be obtained from them. We can scarcely, however, credit, that so great a quantity of water comes from the oil; as this would be a real transmutation; and we know that, besides water, the oils contain also some quantity of fixed air, as well as earth. It is probable, therefore, that, as it is impossible to sustain flame without a decomposition of that part of the air which rushes in to support it, part of the water in this case comes from the air, which always contains moisture in abundance.

Inflammable matters, on being burnt, generally leave behind a small quantity of earthy matter called *ashes*; but to this, spirit of wine, camphor, the more volatile oils, and the mineral oil called *naphtha*, are exceptions. Vegetable substances, when distilled in close vessels, give out a quantity of air, some acid, and an empyreumatic oil, leaving behind a black spongy mass called *charcoal*. To this too there are a few exceptions, *viz.* spirit of wine, and the preparations from it, camphor, and perhaps some of the more volatile oils, or *naphtha*. Animal substances yield only a very fetid empyreumatic oil, and volatile alkali.

In general, all inflammable matters are acted upon with some violence by the vitriolic and nitrous acids, excepting only camphor and *naphtha*. With the vitriolic acid, when in a liquid state, they render it volatile and sulphureous; if in a dry state, they form actual sulphur. With the nitrous, they first impart a high colour and great degree of volatility to the acid; then a violent flame ensues, if the matter is attempted to be dried. With spirit of wine the effects are considerably different; and very volatile compounds are formed, which are called *ether*, on account of their exceeding great disposition to rise in vapour. Similar compounds are likewise produced, but with more difficulty, from the marine acid and concentrated vinegar. The sal sedativus of borax mixes with spirit of wine, and causes it burn with a green flame; but does not seem to produce any other change upon it. How the acid of phosphorus and of ants act upon spirit of wine, is not exactly known; but that of tartar by digestion with it, is converted into the acetous acid. With any other inflammable matter, the phosphoric acid reproduces phosphorus.

There are two singularities observed among the inflammable substances. One is that bituminous matter called *amber*, which yields a volatile salt of an acid nature on distillation: When combined with alkalies, this acid is found to yield compounds similar to those made with the acetous acid and alkali. The other is, that gum called *benzoin*, which is used as a perfume, and yields by sublimation a kind of volatile salt in fine shining crystals like small needles, and of a most grateful odour. These dissolve very readily in spirit of wine; but not at all in water, unless it is made very hot; so that they seem to contain more oily than saline matter.

Neither the nature of these flowers, however, nor that of the salt of amber, is fully known.

SECT. VI. Metalline Substances.

THESE are distinguished from all other bodies by their great specific gravity, exceeding that of the most dense and compact stones. The heaviest of the latter do not exceed the specific gravity of water in a greater proportion than that of 4 to 1; but tin, the lightest of all the metals, exceeds the specific gravity of water in the proportion of 7 to 1. They are also the most opaque of all known bodies, and reflect the rays of light most powerfully.

Metallic bodies possess the quality of dissolving in acids, and uniting with acid salts, in common with earths and alkalies; but, in general, their union is less perfect, and they are more easily separable. They effervesce with acids, as well as calcareous earths and alkalies; but their effervescence is attended with very different appearances. In the effervescence of acids with alkalies, or with calcareous earths, there is a discharge of the fluid called *fixed air*, which is so far from being inflammable, that it will immediately extinguish a candle, or other small flame immersed in it. The mixture also is notably diminished in weight. When a metallic substance is dissolved in an acid, the weight of the mixture is never very much diminished, and sometimes it is increased. Thus, an ounce of quicksilver being slowly dropped into as much aquafortis as was sufficient to dissolve it, and the solution managed so as to take up almost a whole day, the whole was found to have gained seven grains. There is also a remarkable difference between the nature of the vapour discharged from metals and that from alkalies; the former, in most cases, taking fire and exploding with violence; the latter, as already observed, extinguishing flame.

The metallic substances, at least such as we are able to decompose, are all composed of a certain kind of earth, and the inflammable principle called *phlogiston*. The earthy part by itself, in whatever way it is procured, goes by the name of *calx*. The other principle has already been proved to be the same with charcoal. When these two principles are separated from one another, the metal is then said to be *calcined*. The *calx* being mixed with any inflammable substance, such as powdered charcoal, and urged with a strong fire, melts into metal again; and it is then said to be *reduced*, or *revivified*: and this takes place whether the metal has been reduced to a *calx* by dissolution in an acid, or by being exposed to a violent fire. If, however, the calcination by fire has been very violent and long continued, the *calx* will not then so readily unite with the *phlogiston* of the charcoal, and the reduction will be performed with more difficulty. Whether, by this means, *viz.* a long continued and violent calcination, metallic earths might entirely lose their property of combining with *phlogiston*, and be changed into those of another kind, deserves well to be inquired into.

When a metallic substance is dissolved in any kind of acid, and an alkali or calcareous earth not deprived of its fixed air is added, the alkali will immediately be attracted by the acid, at the same time that the fixed

produc-
tions.

Metalline
Substances.

ed air contained in the alkali is disengaged, and the calx of the metal, having now no acid to keep it dissolved, immediately joins with the fixed air of the alkali, and falls to the bottom. Something similar to this happens when metals are calcined by fire. In this case, there is a continual decomposition of the air which enters the fire; and the fixed air contained in it, being, by this decomposition, set loose, combines with the calx; whence, in both cases, there is a considerable increase of weight. If the air is excluded from a metal, it cannot be calcined even by the most violent fire.

524
Reason of
the increase
of weight in
metalline
calces.

When a metal is precipitated by a mild alkali, or by an uncalcined calcareous earth, the reason of the increase of weight is very evident; namely, the adhesion of the fixed air to the metalline calx: but, though it is not so much increased when precipitated by caustic alkali, or by quicklime, there is nevertheless a very evident increase, which is not so easily accounted for. M. Lavoisier has mentioned some experiments made on mercury and iron dissolved in aquafortis, which deserve to be taken notice of, as in a great measure accounting for the phenomenon already mentioned of the solution of metalline substances gaining an addition of weight; and likewise show the proportion of increase of weight with the mild, or calcined calcareous earth.

525
M. Lavoisier's experiments.

"Exactly 12 ounces of quicksilver (says he) were put into a matrafs, and 12 ounces of spirit of nitre poured on it. Immediately a spontaneous effervescence ensued, attended with heat. The red vapours of the nitrous acid arose from the mixture, and the liquor assumed a greenish colour. I did not wait till the solution was entirely accomplished before I weighed it; it had lost one drachm 18 grains. Three hours after, the mercury was nearly all dissolved: but having again weighed the solution, I was much astonished to perceive that it had increased instead of being diminished in weight; and that the loss, which was one drachm 18 grains at first, was now only 54 grains. The next day the solution of the mercury was entirely finished, and the loss of weight reduced to 18 grains; so that in 12 hours the solution, though confined in a narrow necked matrafs, had acquired an augmentation in weight of one drachm. I added some distilled water to my solution, to prevent it from crystallizing; the total weight of it was then found to be 48 ounces 1 drachm and 18 grains.

"I weighed separately, in two vessels, 8 ounces 15 grains of the above solution, each of which portions, according to the preceding experiment, ought to contain 2 ounces of nitrous acid and 2 ounces of quicksilver. On the other side, I prepared 6 drachms 36 grains of chalk, and 4 drachms 36 grains of lime; these proportions having been found by former experiments just necessary to saturate two ounces of nitrous acid. I put the chalk in the one vessel, and the lime in the other.

"An effervescence attended the precipitation by chalk, but without heat; the mercury precipitated in a light yellow powder, at the same time the chalk was dissolved in the nitrous acid. The precipitation by the lime was effected without effervescence, but with heat; the mercury was precipitated in a brownish

powder. When the precipitates were well subsided, I decanted off the liquors from them, and carefullyedulcorated them. After which, I caused them to be dried in a heat nearly equal to that in which mercury boils.

"The precipitate by the chalk weighed 2 ounces 2 drachms 45 grains; that by the lime weighed 2 ounces 1 drachm 45 grains.

"Sixteen ounces of the nitrous acid, the same as employed in the former experiments, were placed in a matrafs, and some iron filings gradually added. The effervescence was brisk, attended with great heat, red vapours, and a very rapid discharge of elastic fluid: the quantity of iron necessary to attain the point of saturation was 2 ounces 4 drachms; after which, the loss of weight was found to be 4 drachms 19 grains. As the solution was turbid, I added as much distilled water as made the whole weight of the solution to be exactly 6 pounds.

"I took two portions, each weighing 12 ounces of the above solution, and containing 2 ounces of nitrous acid, and 2 drachms 36 grains of iron filings. I placed them in two separate vessels. To one were added 6 drachms 36 grains of chalk; and to the other 4 drachms 36 grains of flaked lime, being the quantities necessary to saturate the acid.

"The precipitation was effected by the chalk with effervescence and tumefaction, that by the lime without either effervescence or heat. Each precipitate was a yellow brown rust of iron. They were washed in several parcels of distilled water, and then dried in an heat somewhat superior to that used in the last experiment.

"The precipitate by the chalk, when dried, was a greyish rust of iron, inclining even to white by veins. It weighed 6 drachms 35 grains. That by the lime was rather yellower, and weighed 4 drachms 69 grains.

"The result of these experiments (says M. Lavoisier) are, 1. That iron and mercury dissolved in the nitrous acid acquire a remarkable increase of weight, whether they be precipitated by chalk or by lime. 2. That this increase is greater in respect to iron than mercury. 3. That one reason for thinking that the elastic fluid contributes to this augmentation is, that it is constantly greater when an earth is employed saturated with elastic fluid, such as chalk, than when an earth is used which has been deprived of it, as lime. 4. That it is probable that the increase of weight which is experienced in the precipitation of lime, although not so great as that by chalk, proceeds in part from a portion of the elastic fluid which remains united to the lime, and which could not be separated by the calcination."

But though we are naturally enough inclined to think that the increase of weight in the precipitates formed by lime proceeded from some quantity of elastic fluid or fixed air which remained combined with the lime, it is by far too great to be accounted for in this way, even according to the experiments mentioned by M. Lavoisier himself, and which, from the manner in which they are told, appear to have been performed with the greatest accuracy. He found, that 1 ounce 5 drachms and 36 grains of flaked lime contained 3 drachms and 3 quarters of a grain of water,

526
Consequences
from his
experiments;527
Not well
founded.

Metalline
Substances.

and only 16 grains and an half of elastic fluid were separable from it. In the experiments above related, where only 4 drachms and 36 grains were employed, the quantity of elastic fluid could not exceed 6 or 8 grains. Yet the calx was increased in mercury by no less than 105 grains, and in iron by 203 grains; a quantity quite unaccountable from the elastic fluid or fixed air which we can suppose to be contained in the lime made use of. It is much more probable, that the increased weight of metallic precipitates, formed by lime, arises from an adhesion of part of the acid.

Metals are found to be compounded of a kind of earth mixed with the inflammable principle or phlogiston; and, by a dissipation of the latter, all metallic bodies, gold, silver, and platina excepted, are capable of being reduced to a calx, but very different degrees of heat are required for calcining them. Lead and tin begin to calcine as soon as they are melted, long before they are made red-hot. The same happens to the semimetals bismuth and zinc; the latter indeed, being combustible, cannot bear a greater heat in open vessels than that which is barely sufficient to melt it. Iron and copper require a red heat to calcine them; though the former may be made partly to calcine by being frequently wetted in a degree of heat considerably below that which is sufficient to make it red.

Most metals undergo a kind of spontaneous calcination in the open air, which is called their *rusting*; and which has given occasion to various conjectures. But M. Lavoisier has shown, that this arises from the fixable part of the atmosphere attaching itself to their earthy part, and discharging the phlogiston. According to him, no metallic body can rust but where there is an absorption of air; and consequently metals can be but imperfectly rusted when kept under a receiver.

If two metals are mixed together, the compound generally turns out more fusible than either of them was before the mixture. There are indeed great differences in the degrees of heat requisite to melt them. Thus, lead and tin melt below that degree of heat which is required to make quicksilver or linseed-oil boil. Silver requires a full red heat, gold a low white heat, copper a full white, and iron an extreme white heat, to make it melt. The semimetal called bismuth melts at about 460° of Fahrenheit's thermometer, and tin at about 422° . When mixed in equal quantities, the compound melted at 283° . When the tin was double the bismuth, it required 334° to melt it; with eight times more tin than bismuth, it did not melt under 392° . If to this compound lead is added, which by itself melts in about 540° , the fusibility is surprisingly increased. Mr Homberg proposed for an anatomical injection a compound of lead, tin, and bismuth, in equal parts; which he tells us keeps in fusion with a heat so moderate that it will not singe paper. Sir Isaac Newton contrived a mixture of the above-mentioned metallic substances, in such proportions that it melted and kept fluid in a heat still smaller, not much exceeding that of boiling water. A compound of two parts of lead, three parts of tin, and five of bismuth, did but just stiffen at that very heat, and so would have melted with very little more; and when the lead, tin, and bismuth, were to one ano-

ther in the proportions of 1, 4, and 5, the compound melted in 246° . We have seen, however, a piece of metal compounded of these three, the proportions unknown, which melted, and even underwent a slight degree of calcination, in boiling water, and barely stiffened in a degree of heat so gentle that the hand could almost bear it.

A slight degree of calcination seems to give the acids a greater power over metalline substances; a greater makes them less soluble; and if long and violently calcined, they are not acted upon by acids at all. Of all the acids, the marine has the greatest attraction for metallic calces, and volatilizes almost every one of them.

Sulphur readily unites with most metals, destroys their malleability, and even entirely dissolves them. On gold and platina, however, it has no effect, till united with a fixed alkaline salt, when it forms the compound called *hepar sulphuris*; which is a very powerful solvent, and will make even gold and platina themselves soluble in water, so as to pass the filter. This preparation is thought to be the means by which Moses dissolved and gave the Israelites to drink the golden calf which they had idolatrously set up.

When a metal is dissolved in an acid, it may be precipitated, not only by means of calcareous earths and alkalies, but also by some other metals: for acids do not attract all metals with equal strength; and it is remarkable, that when a metal is precipitated by another, the precipitate is not found in a calcined state, but in a metallic one. The reason of this is, that the precipitating metal attracts the phlogiston which is expelled from that which is dissolving, and immediately unites with it, so as to appear in its proper form. The various degrees of attraction which acids have for the different metals is not as yet fully determined. The best authenticated are mentioned in the Table of Affinities or Elective Attractions (Sect. IX.)

Metalline substances are divided into metals and semimetals. The metals which are distinguished from the semimetallic substances by their malleability or stretching under the hammer, are in number seven; gold, silver, copper, iron, lead, tin, and platina. To these is added quicksilver; which Mr Brown's experiments have shown to be a real malleable metal, as well as others, but requiring so little heat to keep it in fusion, that it is always found in a liquid state. The semimetals are bismuth or tin-glass, zinc, regulus of antimony, and cobalt, nickel, and arsenic. This last substance is now discovered to be compounded of an acid of a peculiar kind and phlogiston; and as the quantity of the latter is great or small, the arsenic assumes either a metallic or saline form. It likewise unites with sulphur, with which it forms a compound of a red or yellow colour, according as more or less sulphur is used. This compound is easily fusible; though the arsenic, by itself, is so volatile as to go all off in vapour rather than melt. In common with the salts, it possesses the properties of dissolving in water, and uniting itself to alkalies. Water will dissolve about $\frac{1}{7}$ of its weight of pure arsenic; but if arsenic is boiled in a strong alkaline lixivium, a much greater proportion will be dissolved. Indeed strong alkaline lixivia will dissolve

Waters, &c. solve a part of almost every metalline substance, except gold, silver, and platina; but, excepting copper, which may be formed into crystals by means of the volatile alkali, none of them will assume a crystalline form when united with alkalies. Arsenic, on the contrary, unites very readily with fixed alkalies, and shoots with them into a neutral salt. If it is mixed with nitre, it unites itself to the alkaline basis of that salt, and expels the acid in very volatile fumes, which are difficultly condensed into a blue liquor. The reason of this is the great attraction between the nitrous acid and phlogiston, which are always disposed to unite when a proper degree of heat is applied. Was the phlogiston contained in large quantity in the arsenic, and the heat sufficiently great, a violent deflagration would ensue; but as the acid of arsenic attracts the alkaline part of the nitre, at the same time that the nitrous acid attracts the phlogiston, a double decomposition ensues, in a less degree of heat than would otherwise be necessary; and the nitrous acid arises in a very volatile state, as it always is when combined with phlogiston, which is the occasion of the blueness in aquafortis so produced. The arsenic is also decomposed by being deprived of its proper quantity of phlogiston; in consequence of which its acid attaches itself to the fixed alkali of the nitre, and forms a neutral arsenical salt. For the extraction of metallic substances from their ores, and the various methods of refining them, see METALLURGY.

SECT. VII. *Waters.*

THE pure element of water, like that of fire, is so much an *agent* in most chemical operations, as to be itself very little the *object* of practical chemistry. Some late experiments, however, have shown that this fluid really consists, in part at least, of phlogiston, and an invisible substance which forms the basis of pure air; and consequently water is generated in the deflagration of dephlogisticated air; but as the basis of the former cannot be perceived by itself, we can as yet say nothing about it. Waters, therefore, can only be the objects of chemistry, in consequence of the impurities they contain: and as these impurities are most commonly of the saline kind, it is impossible that any general theory can be given of waters, distinct from that of the salts contained in them; which all depend on the general properties belonging to salts, and which we have already mentioned. Any thing that can be said with regard to waters, then, must be postponed to the particular consideration of the properties of each of the saline bodies with which water is capable of being adulterated. We shall therefore refer entirely to the article WATER in the order of the alphabet, for what can be said on this subject.

SECT. VIII. *Animal and Vegetable Substances.*

THE general chemical properties of these have been already taken notice of under the name of *inflammable substances*. They agree in giving out a very thick fetid oil, when distilled by a strong fire; but in other respects they differ very considerably. Most kinds of vegetables give out an acid along with the oil; but all animal substances (ants, and perhaps some other insects, excepted) yield only a volatile alkali. Some kinds of

vegetables, indeed, as mustard, afford a volatile alkali on distillation, similar to that from animal substances; but instances of this kind are very rare, as well as of animals affording an acid. Both animal and vegetable substances are susceptible of a kind of fermentation, called *putrefaction*, by which a volatile alkali is produced in great plenty: there is, however, this remarkable difference between them, that many vegetable substances undergo two kinds of fermentation before they arrive at the putrefactive stage. The first is called the *vinous*, when the ardent spirits are produced, which we have already mentioned when speaking of inflammable substances. This is succeeded by the *acetous*, wherein the vegetable acid called *vinegar* is produced in plenty: and lastly, the putrefactive stage succeeds when a volatile alkali is only produced; not the smallest vestige either of ardent spirits or of vinegar remaining. On the other hand, animal substances seem susceptible only of the putrefactive fermentation; no instance having ever occurred where there was the least drop, either of ardent spirit or of vinegar, produced from a putrified animal substance. (See FERMENTATION and PUTREFACTION.)

SECT. IX. *Of the Chemical Characters, and Tables of Elective Attraction.*

THE numerous *marks* or *characters* by which the ancient chemists used to denote many different substances, were invented rather from a superstitious and fantastical principle than from any real necessity; or, perhaps, like the enigmatical language used by the alchemists, they have thereby sought to conceal their mysteries from the vulgar. In contriving these marks, they affected a great deal of ingenuity; intending them as symbols of the qualities possessed by each of the different substances. A circle being supposed the most perfect figure, was therefore used to represent the most perfect metal in nature, that is, *gold*. Silver being likewise a perfect and indestructible metal, is placed next to gold; but, on account of its inferiority, is expressed only by a crescent, as if but half gold. A circle was likewise used to denote salt of any kind, as being something elaborate and perfect. A cross was used to denote acrimony of any kind, and consequently employed for the acrimonious salts of vitriol, alkali, &c. Hence all the inferior metals have the cross some how or other combined with the marks designed to represent them. Thus, the mark for quicksilver denotes, that it hath the splendor of silver, the weight of gold, but its perfection is hindered by an acrimony represented by the cross at bottom, &c. Fire is represented by an equilateral triangle, having one of its angles uppermost. This may be considered as a rude representation of flame, which is always pointed at top. Water, again, is represented by a triangle, with an angle downwards, showing the way in which that element exerts its strength, &c. All these marks, however, as they were of no real use at first, so they are now becoming every day more and more neglected. Such of them, however, as may most readily occur in chemical books are represented and explained on Plate CXXXII.

The French chemists have of late attempted to introduce a kind of new chemical language; and by adopting it themselves, may perhaps make it at last universal,

verfal, as it is now impossible to understand their writings without knowing it. See the Table at the end of this article.

Tables of affinities, or elective attractions, are but of late invention. They are consequences of an improved state of chemistry, when the different substances were found to act upon one another in most cases according to a fixed and settled rule. The most approved table of this kind for a long time was that composed by Mr Geoffroy. It was, however, found to be very incomplete, not only as to its extent, but likewise as heat and some other circumstances were found to vary the attractions considerably, and sometimes even to reverse them. Other tables have been constructed by Mr Gellert, &c. but none hath yet appeared so complete but that many additions may be made to it. The following is that at present exhibited by Dr Black in his course of chemistry.

1. VITRIOLIC ACID.

III. Those which happen in mixtures by fusion.

1. {	Tin	Iron
	Silver	Lead.
2. {	Copper	Sulphur
	Gold	Lead.
3. {	M. S.	Sulphur
	Gold	Reg. of ant.

The first of these tables requires very little explanation. The names printed in small capitals, are those of the substances which have the affinity with or attract those below them. Thus, vitriolic acid attracts most powerfully the phlogiston, or inflammable principle; next, fixed alkali; then, calcareous earth; and so on, in the order in which they are marked.—The tables of double elective attractions cannot be made quite so distinct; though an explanation of one example will make this likewise easy to be understood. Thus in Table I. the first case is, “If a combination of acids with calcareous earths or metallic substances is mixed with a combination of volatile alkali and fixed air, the acids will unite themselves to the volatile alkali, and the fixed air to the calcareous earth or metallic substance.

SECT. X. *Of the different Operations in Practical Chemistry, and the proper Instruments for performing each.*

554
Operations
in chemi-
stry.

THE most remarkable operations in chemistry, and by which the greatest changes are made upon those bodies which are the objects of that science, may be comprehended under the following names. 1. Solution. 2. Filtration. 3. Precipitation, or coagulation. 4. Evaporation. 5. Crystallization. 6. Distillation. 7. Sublimation. 8. Deflagration. 9. Calcination. 10. Fusion. 11. Maceration, or digestion. To which we may add, 12. Trituration, or levigation.

555
Chemists,
how divid-
ed.

Before we proceed to a particular account of each of these operations, it is necessary to take notice, that there are two different things proposed by those who enter on the practice of chemistry. Some have nothing farther in view than the enlargement of their knowledge, or making improvements in arts which are to be practised by others for their own advantage. Others design to follow chemistry as a trade, by which they hope to enrich themselves, or to get a comfortable livelihood. But the apparatus and utensils necessary for performing the very same operations are exceedingly different when experiments only are to be made, from what they must be when these operations are performed with a view to profit; and so great is this difference, than those who pursue chemistry with a view to advantage, will always find themselves very considerable losers if they follow the plan of an apparatus or a laboratory designed only for making experiments. Along with the apparatus, therefore, which is commonly described in chemical books, and proper only for experiments, we shall also give that which is necessary for preparing great quantities of any chemical article in the way of trade.

556
Glas vessels,
when
to be used.

In general, those who practice chemistry merely with an experimental view, ought, as much as pos-

sible, to make use of glass vessels, as not being liable to be corroded by the most powerful solvents; and, by their transparency, giving an opportunity of observing what passes within them during the operation. But by those who practise chemistry with a different view, these vessels ought, with equal care, to be avoided, on account of their expence and brittleness. This last quality, indeed, is possessed by glass in so eminent a degree, that glass vessels will sometimes fly to pieces, and that with considerable violence, when standing by themselves, and nothing touching them. The principal objects which a chemist ought to have in view, in performing his operations, ought to be to save time and fuel, especially the former; and for this purpose, he would find himself a considerable gainer, though he should be at much greater expence in his apparatus than he would otherwise have occasion for.

On the subject of chemical vessels Dr Black observes, that “with regard to the material of which these are composed, we are very much at a loss; and indeed there are no such materials in nature as are capable of answering the purposes of chemists in absolute perfection.—The qualities are, 1. Transparency, to allow us to see the changes going on; 2. The power of resisting the action of acids and corrosive substances; 3. That they bear sudden alterations of heat and cold without breaking; 4. That they be strong, in order to confine elastic vapours; and, 5. That they bear very great heat without melting. As these qualities, however, are not to be met with united in any one substance, the chemists are obliged to have recourse to different substances which possess some of them differently. These are, *glass, metal, and earthen ware*. Glass is possessed of the two first properties, but has the inconvenience of being apt to crack and fly in pieces, on any sudden transition from heat to cold, or from cold to heat. The best method of remedying this defect, is to have the glass made very thin, and of a round figure, that it may be all heated as equally as possible; as it is the unequal application of the heat which causes it break. Another requisite in the choice of chemical glasses, is that they be well annealed. If this is not done, the glass will either immediately fly to pieces, or be liable to break on the smallest accident. That such glasses should be liable to be broken on every slight occasion, is a phenomenon that has hitherto received no explanation. If you touch them with a diamond, with a piece of flint, glass, &c. or expose them to the heat of the sun, they break immediately. Dr Black has had great vessels of glass, which broke immediately on his throwing a little sand into them to clean them. This manifestly depends upon the same principles as the qualities of what are called *glass tears*.

Glass when well annealed is universally to be preferred, where great and sudden changes of heat, or much strength, are not required. Flint-glass is the best; but the coarser kinds, as bottle-glass, are very apt to break.

The metals have the third and fourth qualities in perfection, but are deficient in all the rest. The most troublesome property is, that they are liable to be corroded by acids and other bodies, as is the case with iron and copper; though this is in some

measure

Chemical
Operations.

measure remedied by tinning; which, though it wants some of the qualities from its melting too soon, yet resists the action of many acrid substances without being so readily injured by them; but it is not entirely free from this imperfection, and is liable to be somewhat corroded and rusted. In nice operations, therefore, recourse is had to silver and even to gold vessels.

361
Of earthen
ware.

Earthen ware possesses only the fifth quality in perfection, viz. that of bearing a violent heat without fusion. The basis of these vessels is clay, which, when good, is very convenient for the formation of vessels, and it has been used from the earliest ages of chemistry for this purpose. The requisite qualities are, 1. A considerable degree of toughness when mixed with water. 2. A great degree of hardness when burnt in the fire with a violent degree of heat. The best kind of clay thus contracts a degree of hardness scarce inferior to flint, as is the case with that of which tobacco-pipes are made; but most other kinds, such as that of which bricks are constructed, are apt to melt with a strong heat into a spongy matter. Clay, however, can seldom be used alone; for when burnt to extreme hardness, the vessels are very liable to crack. This is remedied by mixing sand reduced to a particular degree of fineness, with the clay of which the vessels are made. For this purpose both the finest and the coarsest particles of the sand must be thrown away.

362
Black lead
a valuable
material for
some pur-
poses.

Another substance known by the name of black lead, used in the making of pencils, resists the fire exceedingly. This, however, does not contain an ore of lead, but sulphur, and some mineral substances; when mixed with clay, however, it makes it resist the fire surprisingly. But there are some particular cases in which neither sand nor black lead can be used as a material; for the sand is easily corroded by acrid matters, and the black lead would produce other inconveniences. Clay is therefore to be taken in its unburnt state, reducing it to a powder like sand; then burning this powder with a violent heat, so as to convert it into sand. Mixing it then with raw clay, it forms a composition which answers very well for making chemical vessels, and may be employed in those particular cases where sand would not answer. Pott of Berlin has written upon the different kinds of earthen ware proper to be employed in the construction of chemical vessels. There is a French translation of it in four or five volumes. In cases where the utmost compactness of texture is required, porcelain vessels are to be chosen; which is composed of the finest clay, mixed with a stony matter, that has the quality of melting in a violent heat, and gives more compactness to the clay than it is naturally capable of receiving; but these are rather too costly for most operations. Reaumur has taught a way of converting glass into porcelain.

363
Porcelain
vessels when
to be used.

We shall now proceed to a particular description of each of the operations above mentioned.

364
Solution.

I. SOLUTION. By this is understood the dissolving a solid substance in a fluid, so as that the solid shall totally disappear, and become part of a transparent liquor. This operation applies particularly to salts, earths, and metals; as well as to several unctuous and inflammable substances. For performing this operation in a small way, common vials are in many cases sufficient. Where

N^o 71.

the solution is attended with effervescence and a discharge of vapours, the long-necked glasses called *matrasses*, or *bolt-heads*, (fig. 5.), are necessary. Florence flasks are indeed exceedingly well adapted for this operation, as being of the proper shape, and capable of bearing heat so well, that they may be filled with any fluid, and set on a common fire like a metalline vessel. Solution is much promoted by agitating the vessel, and by heat. In some cases, indeed, it will not take place till the mixture becomes very hot; and in such cases it will be proper to make the fluid boiling hot by itself, and then slowly to add the substance to be dissolved.

When large quantities of saline matter are to be dissolved, metalline vessels must be used: but before any are made use of for this purpose, it will be necessary to make an experiment whether the salt receives any impregnation from the metal of which the vessel intended to be made use of is formed; and if this is found to be the case, it must not be used. The metals most liable to be corroded by saline bodies are iron and copper; and indeed, unless it be for the single purpose of dissolving fixed alkaline salts, iron vessels seem totally unfit for saline solutions of any kind. Copper vessels are also very liable to be corroded, and to communicate very mischievous qualities to the liquors which corrode them; for which reason, they ought never to be made use of for the purposes of solution. The metal least liable to be corroded, next to gold and silver, is lead; and therefore a chemist ought rather to provide himself with leaden vessels than those of any other metal. But though lead is not apt to be corroded by many kinds of salts, there are some which are found to act upon it, and to form therewith a very dangerous poison. The vegetable acid of vinegar is particularly apt to receive a dangerous impregnation from this metal; and therefore no solution of any salt containing this acid ought to be made in leaden vessels. It appears to be very little affected by the vitriolic or marine acids; and therefore any saline substance containing either of these acids may be safely enough dissolved in vessels made of lead.

In order to save time in making solutions, the vessels ought to be as large as possible; though even in this there must be a certain limit: for two small vessels filled with water will sooner acquire the necessary degree of heat than one large one; and in proportion as the vessel is made more capacious, the sides and bottom must be thicker, which considerably increases the expence. Fifteen or twenty English gallons is the utmost capacity of which they ever will be required; and is rather above what will on most occasions be necessary. They ought to be of a conical figure, round at the bottom; and to have a cover of thick plate-iron all around that part which is exposed to the action of the fire, that the lead may not bend on the application of heat, which it would otherwise be very apt to do. When the solution is to be made, the leaden vessel is first to be filled up with water so far as to have room for the quantity of salt intended to be dissolved: a fire is then to be applied so as to make it boil: and then the salt is to be added slowly, so as scarcely to hinder the boiling; for if a great quantity was thrown in at once, so as to cool the liquor very much, great part of the salt would concrete on the bottom, in such

Chemical
Operations

a manner as not only to be very difficultly soluble, but even to endanger the melting of the vessel. It is of some consequence also to avoid the hot steam which proceeds from the boiling water, and which issues with great force from a narrow-mouthed vessel such as we have been describing. That the operator may be out of the reach of this, and likewise dissolve the salt in a regular and gradual manner, without any danger of its concreting on the bottom, it will be proper to have a leaden, or even a wooden, vessel, with a long handle; which is to be filled with the substance to be dissolved, then immersed in the boiling liquor, and shaken about in it, till the salt is made into a kind of thick pap, which will be in no danger of concreting. It will also be proper not to saturate the water perfectly with salt; for it will in that case be impossible to hinder part of it from settling on the bottom, where it soon acquires such a degree of heat as to melt the lead. Before any saline substance is put into water for solution, it ought to be pounded and sifted through a hair sieve.

Where large quantities of metal are to be dissolved in acids, especially the nitrous acid, glass vessels are in a manner indispensable; although the common stone-ware bottles, especially those made in Holland, will answer the purpose very well, as not being liable to corrosion, and not so apt to break as the glass vessels are. They may be got of such a size as to hold three or four gallons: but no vessel in which metalline solutions are made ought ever to be above half full.

In solutions of oily and inflammable substances, cast iron vessels are perhaps the most proper of any; though copper ones are generally preferred. The copper is excessively soluble in oil, especially if it is left to cool in such a vessel; but iron is not soluble in any inflammable matter except sulphur. Copper has, however, this advantage over iron, that it is sooner cooled, as the vessels made of copper are thinner than they can be made of cast iron: so that if too great heat is applied to a copper vessel, it may be easily remedied by taking it off the fire; but in a cast iron vessel the heat continues so long as may sometimes produce dangerous consequences, even after the fire is removed.

565
Dr Black's
directions
for solution.

Dr Black observes, that for the purpose of solution, if no particular nor uncommon consequence follow the application of the two bodies to each other, and if none of them be very volatile, any glass or porcelain vessel that can resist the action of the substances will answer the purpose; but it often happens that they break out into violent ebullition, which produces steam; and here a common vessel is not so proper, as we would wish to have the vapour confined or condensed. We therefore choose a close vessel that will bear the heat suddenly produced by the mixture, or the heat that may be necessary to promote the action of such bodies upon one another. Of this kind is the *phiala chemica*, or matrafs, in which the vapours will have time to circulate and to be condensed again, without being allowed to escape. Where the matter is in small quantity, smaller vessels somewhat of the same form are used, as Florentine flasks, which bear sudden changes of heat and cold remarkably well, on account of their thinness. In order to promote the action of bodies, it is sometimes necessary to make the fluids boil; and for

VOL. IV. PART II.

this purpose we must have a matrafs with a large neck, or apply another vessel to it that will receive these steams, and give them still more room for their condensation, and direct them to fall back again, when condensed, into the matrafs. This is called *circulation*. Macquer describes another vessel called the *pelican*, which has been made use of for this purpose; but it is hardly ever employed, on account of its being so troublesome to procure and manage it; and the advantages arising from it may be obtained by a more simple apparatus.

To this head we must refer Papin's digester, which is represented Fig. 4. It is generally made of copper, very thick and strong, open at the top, with a lid fitted to it, which applies very exactly. There are usually two projections on the side, designed to make the lid go in a particular manner, but they are unnecessary. There are other two, to which are fitted the two sides of a cross bar BB; in which cross bar there is a strong screw D, by which the lid can be pressed down very strongly. Its use is to force water to bear a stronger heat than it can do under the ordinary pressure of the atmosphere. It is sometimes furnished with an apparatus for letting out the steam, lest it should be in danger of bursting the vessel. A pipe is passed through the lid which is fitted with a valve, on which passes a lever at a very small distance from its centre of motion; and this can be made to press on the valve with different weights, according to the distance of these weights from the centre. In one constructed by Dr Black, there was another pipe below, into which a thermometer could be introduced, in order to measure the degree of heat to which the steam was raised. This machine was pretty much employed some time ago, and its effects were much admired; but we find that most things which can be dissolved in this way, can likewise be dissolved in the ordinary way by boiling water, provided it is continued for a longer time, as animal bones, from which the gelatinous parts are indeed extracted very quickly by this vessel; but the same change is produced by boiling them in water for a long time in the ordinary degree of heat.

II. FILTRATION. This operation is generally the attendant of solution: very few substances, of the saline kind especially, are capable of being dissolved without leaving some impurities, from which they must be freed; and the doing of this, so as to render the solution perfectly transparent, is what is understood by the word *filtration*.

For purposes merely experimental, a glass funnel and piece of paper are generally sufficient. The paper is formed into a conical cap, which being placed in the funnel with its point downwards, the funnel is then placed in the mouth of a vial; and the solution or other liquor to be filtered is poured into the paper cap, through which the liquor passes transparent, leaving its impurities on the paper. For the purpose of filtration, paper has come into such general use, that a particular kind of it is prepared under the name of *filtering paper*. This is of a reddish colour; but Dr Lewis prefers the whitish grey paper, which comes from Holland about the pill boxes, as not giving any colour to the solutions which pass through it.

This operation, though apparently so simple and easy,

Chemical
Operations.566
Pelican.

Filtration.

Chemical
Operations.

easy, is nevertheless attended with very troublesome circumstances, on account of the great time it takes up. Even where very small quantities of liquor are to be filtered, merely for experiment's sake, the impurities frequently settle on the paper so soon, and obstruct its pores to such a degree, that the operator is often quite wearied out: often, too, the paper breaks; and thus the whole is spoiled, and the operation must be begun over again.

To avoid these inconveniences, another method of filtration hath been proposed; namely, to use a number of cotton threads, the ends of which are to be immersed in the liquor, and the other ends are to hang over the side of the vessel which contains it, and to hang lower than the surface of the liquor. By this means they will act as so many capillary syphons, (see *SYPHON*); the liquor will arise in them quite pure, and be discharged from their lower extremities into a vessel placed to receive it. That the liquor may flow freely into the cotton, it will be proper to wet the threads before they are used.

In point of efficacy, no doubt, this method excels every other; and where the operator has abundance of time and patience, may be proper for experiments; but, in the way of trade, such a contrivance is evidently useless. For filtering large quantities of liquor, therefore, recourse has been had to large funnels; earthen cullenders, or basons full of holes in the bottom, lined with filtering paper; and to conical bags of flannel or canvas.

The inconveniences attending funnels, when used only in the way of experiment, are much greater when they are employed for filtering large quantities of liquor; and therefore they are generally laid aside. The earthen cullenders, too, do not answer any good purpose; nor indeed does filtration through paper in general succeed well. The conical flannel or canvas bags are greatly preferable: but they have this inconvenience, that the pressure of the liquor is directed chiefly against one particular point, or a small part of the bottom, and therefore the impurities are forcibly driven into that place; and thus the operation becomes insufferably tedious.

The best method of obviating the inconveniences of filtration seems to be the following. Let a wooden frame of about three feet square be made, having four holes, one in each corner, about three quarters of an inch in diameter. This frame is to be supported by four feet, the ends of which must project an inch or two through the holes. Thus the whole may be occasionally set up and taken down, so as to go into very little compass; for if the feet are properly placed, each with a little projection outwards, there will be no danger of its falling. A square piece of canvas must also be procured, somewhat less than the wooden frame. On each corner of it there must be a very strong loop, which slips on one of the projecting ends of the feet, so that the canvas may hang a little slack in the middle of the frame. The liquor to be filtered is now poured into the canvas, and a vessel placed underneath to receive it. At first it will pass through very foul; but being returned two or three times, will become perfectly transparent, and will continue to run with great velocity, if the filter is kept constantly full. A filter of the size just now

mentioned will contain ten gallons of liquid; which is a very great advantage, as the heat of such a quantity of liquor is not soon dissipated, and every solution filters much faster when hot than when allowed to cool.

The advantages of a filter of this kind above others arise from the pressure of the liquor being more equally diffused over a large space, by which the impurities are not forced so strongly into the cloth as to stop it up entirely. Yet even here, where large quantities of liquor require filtration, the cloth is apt to be stopped up so as to make the operation not a little tedious and disagreeable. It will be proper therefore to have several cloths, that one may be applied as soon as another is taken off.

To promote the operation of filtration, it is very proper to let the liquors to be filtrated settle for some time; that so their grosser feculencies may fall to the bottom, and thus there will be the fewer to retard the last part of the operation. Sometimes, however, these feculencies refuse to settle till after a very long time; and where this happens to be the case, a little powdered quicklime thrown into the boiling liquor remarkably promotes the separation. This, however, can only be used in certain cases.

In some cases, the discovery of a ready way of filtering a large quantity of liquor would be a matter of great consequence; as where a town is supplied with river water, which is generally far from being clear, and often imparts a disagreeable colour to clothes washed with it. Some years ago, a scheme was proposed by a chemist for filtering muddy water in any quantity. His method was, to have a large cask covered over in the bottom with straw to the depth of some inches, and then filled up with sand. This cask was entirely open at one end, and had a hole in the other, which, by means of a leaden pipe, communicated with a large reservoir of the water to be filtered, and which stood considerably higher than the cask. The water which descended through the pipe into the cask, having a tendency to rise up to the same level with that in the reservoir, would press violently against the sand, and, as he thought, run over the mouth of the cask perfectly filtrated, and free from its impurities. By this contrivance, indeed, a very violent pressure was occasioned, if the height of the reservoir was considerable: but the consequence was, not a filtration, but a greater degree of impurity in the water; for the sand was forced out of the cask along with it, and, however confined, the water always rose as muddy as it went in.

Where water is to be filtered in large quantity, as for the purposes of a family, a particular kind of soft spongy stones, called *filtering stones*, are employed. These, however, though the water percolates through them very fine, and in sufficient quantity at first, are liable to be obstructed in the same manner as paper, and are then rendered useless. A better method seems to be, to have a wooden vessel, lined with lead, three or four feet wide at top, but tapering so as to end in a small orifice at the bottom. The under part of the vessel is to be filled with very rough sand, or gravel, well freed from earth by washing. Over this, pretty fine sand may be laid to the depth of 12 or 14 inches, but which must likewise be well freed from earthy particles.

569.

filtering
large quan-
tities of wa-
ter.

Chemical
OperationsChemical
Operations.

particles. The vessel may then be filled up to the top with water, pouring it gently at first, lest the sand should be too much displaced. It will soon filter thro' the sand, and run out at the lower orifice exceedingly transparent, and likewise in very considerable quantity. When the upper part of the sand begins to be stopped up, so as not to allow a free passage to the water, it may occasionally be taken off, and the earthy matter washed from it, when it will be equally serviceable as before.

570
Precipitation.

III. PRECIPITATION, OR COAGULATION. This operation is the very reverse of solution, and is the bringing a body suddenly from a fluid to a solid state. It differs from crystallization, in that it generally requires less time; and in crystallization the substance assumes regular figures, whereas precipitates are always in the form of powders.

Precipitation is generally preceded by solution and filtration: it is used for separating earths and metals from the acids which had kept them suspended. When a precipitation is made of the more valuable metals, glass vessels are to be used. When earths, or the imperfect metallic substances, are to be precipitated in large quantity, wooden ones answer every purpose. If a metal is to be precipitated by an alkali, this salt must first be dissolved in water, then filtered, and gradually added to the metallic solution. If particular circumstances do not forbid, the salt for precipitation should be chosen in its caustic state, or deprived of its fixed air, because then a very troublesome effervescence is avoided. To promote the operation also, the mixture, if contained in a glass, is to be shaken; or if in any other vessels, to be well stirred after every addition of alkali. If an earth is employed to precipitate a metal, the mixture must be in a manner constantly stirred or shaken, in order to promote the precipitation: and if one metal is to be precipitated by another, that which is used as a precipitant must be beaten into thin plates, that so they may be frequently cleaned from the precipitating metal, which would otherwise very soon totally impede the operation.

Sometimes a precipitation ensues on the addition of water or spirit of wine: but in most cases care must be taken not to add too much of the substance which is used to precipitate the other; because, in such a case, the precipitate may be dissolved after it has been thrown down. Thus, though volatile alkali will separate copper from aquafortis, it will as effectually dissolve the precipitate, if too much of it is used, as the acid itself. It is proper, therefore, to proceed cautiously, and examine a small quantity of the liquor from time to time. If an addition of the precipitant throws down any more, it will be proper to add some more to the whole solution.

571
Edulcora-
tion.

It is seldom or never that precipitation can be performed so perfectly, but that one or other of the ingredients will prevail; and though they should not, a new compound, consisting of the acid united with the alkali, or other substance used for precipitation, is contained in the liquor through which the precipitate falls. It is proper, therefore, to wash all precipitates; otherwise they can never be obtained perfectly pure, or free from a mixture of saline substances. This is best done by pouring the whole into a filter, and letting the fluid part run off, as long as it will drop, with-

out shaking the cloth. Some water is then to be cautiously poured all over the surface of the precipitate, so as to disturb it as little as possible. This water will push before it the saline liquor which is mixed with the powder, and render it much purer than before. A second or third quantity of water may be used, in order to wash off all the saline matter. This is called *edulcorating* the precipitate.

IV. EVAPORATION. This operation consists in dissipating the most fluid or volatile parts of any substance by means of heat. It most generally succeeds solution and filtration, being a preparatory for the operation of crystallization.

572
Evapora-
tion.

For the evaporation of saline solutions, which have been already filtered, and which it is of consequence to preserve from even the least impurities, distilling vessels are unquestionably the most proper; both as, by their means, the solution will be kept perfectly free from dust, and as the quantity of liquor evaporated can be known with certainty by measuring that which comes over. This also is probably the most expeditious method of evaporating, and which requires the least fuel. (See the detached articles EVAPORATION and DISTILLATION). With regard to vessels for evaporation, the same thing must be applicable which was mentioned above under *Solution*. No saline liquor must be evaporated in a vessel which would be corroded by it; and hence iron vessels are absolutely improper for evaporations of any kind of saline liquor whatever.—Lead is in this case the metal most generally useful. It must only be used, however, where the evaporation is not carried to dryness; for, on account of the great fusibility of this metal, nothing could be exsiccated in it without great danger of its melting. Where a saline liquor therefore is to be perfectly exsiccated, the evaporation, if performed in lead vessels, must be carried on so far only as to form a saline pellicle on the surface of the liquor. It is then to be drawn off; for which purpose, all evaporating vessels should have a cock near the bottom. The liquor must now be put into a number of stone-ware basons, set on warm sand, where the exsiccation may be finished.

V. CRYSTALLIZATION. This, though commonly accounted one of the processes in chemistry, is in reality only a *natural* one, and which the chemist can only prepare for, leaving the operation entirely in the hands of nature.—By crystallization is meant the separation of a salt from the water in which it has been dissolved, in transparent masses regularly figured, and differently formed, according to the different nature of the salts.

573
Crystalliza-
tion.

This process depends upon the constitution of the atmosphere more than any other; and therefore is difficult to be performed, nor does it always succeed equally well; neither have there yet been laid down any rules whereby beautiful and regular crystals can with certainty be formed at all times.

As the different salts assume very different figures when crystallized, they are not subject to the same general rules in crystallization. Nitre, Glauber's salt, vitriol of iron, and many others, crystallize best on having their solutions set in a cold place after proper evaporation. Sal polychrest, and common salt, require the solution to be kept as hot as the hand can bear it during the time of crystallizing. Soluble tartar too,

and other deliquescent salts, require to be kept warm while this operation is going on; and there are many saline substances, such as the combinations of calcareous earths and magnesia with acids, which can scarcely be crystallized at all.

Mr Beaumé has discovered, that when two or more salts are dissolved in the same quantity of water, when one crystallizes, the crystals of that salt will not contain the least quantity of any of the others; neither, although the liquor was acid or alkaline, will the crystals for that reason be either acid or alkaline, but will remain perfectly neutral; and the acid or alkaline liquor which adheres to the outside of the crystals may be absorbed by merely spreading them on filtering paper.—Hence we are furnished with a better method of shooting salts into large and well formed crystals than merely by dissolving them in water; namely, by adding to the solutions, when set to crystallize, a certain quantity of acid or alkaline liquor, according to the nature of the salts themselves. These additions, however, are not equally proper for all salts; and it is not yet determined what kinds of salts ought to be crystallized in alkaline, and what in acid liquors.—Soluble tartar and Seignette's salt crystallize best when the liquor is alkaline. Sal sedativus, sal Glauberi, and sal polychrest, require an acid if crystallized in the cold; but sal polychrest forms into very fine and large crystals when the solution is alkaline, and kept as hot as the hand can easily bear.

The best general direction that can be given with regard to the regular crystallization of salts is, that they ought to be set to crystallize in as large a quantity at once as possible; and this, as far as we have observed, without any limit; for by this means, the crystals are formed much larger and better figured than they possibly can be by any other method hitherto known.—As to the form of the vessels in which salts are to be crystallized, little can be said with certainty. They are generally flat, and wider at top than at the bottom. The only proper material, in the large way, is lead.

VI. DISTILLATION. This is a kind of evaporation; only in such a manner, that the part of the liquor evaporated is not dissipated in the air, but preserved by making the steam pass through a spiral pipe, which goes through a large vessel full of cold water, or into cold glass receivers.

This is one of the most common chemical operations; and as there are a variety of subjects which require to be distilled, there is consequently a considerable variety both in the form of the distilling vessels to be used on different occasions, and likewise in the materials of which they are made, as well as the management of the fire during the time of the operation.

The most simple and easily performed distillation is that by the common copper still, (fig. 3). It consists of two parts; one called the *body*, and the other the *head*. The body is a cylindrical vessel of copper, which is sometimes tinned over in the inside; but where distillation is performed without any regard to the residuum, the tinning is useless. The upper part of the body terminates in a kind of arch, in the middle of which is a circular aperture, about one half, or something less, in diameter, of the breadth of

the whole body.—Into this aperture, a round head, made likewise of copper, is fitted, so as to be removable at pleasure. In the top, or sometimes in the side of the head, is inserted a pewter pipe, which communicates with a spiral one of the same metal, that passes through a large wooden vessel, called the *refrigeratory*, filled with cold water; each of its ends projecting a little above and below. The still is to be filled two thirds full of the substance to be distilled, the head put on, and the junctures well closed with a mixture of linseed meal and water, or common flour or chalk and water will answer the same purpose. This mixture is called the *luting*, or *lute*. A fire being kindled under the still, the vapours will arise; and, being condensed by the cold water through which the spiral pipe called the *worm* passes, will run in a stream more or less strong as the fire is more or less hastily urged, and is caught in a receiver set underneath.

This kind of distilling vessels is proper for procuring the essential oils of vegetables, vinous spirits from fermented liquor, and for the rectification of these after they are once distilled. Even the acetous acid may be very conveniently distilled in a copper vessel, provided the worm and all the descending parts of the pipe which communicates with it be of pewter, otherwise a mischievous impregnation of copper would be communicated to the distilled vinegar. The reason of this is, that copper is not dissolved by vinegar, or in very small quantity, when that acid is boiled in it; but if the metal is exposed to the action of the acid when cold, or to its vapours, a considerable dissolution takes place. For this reason, too, the still must be washed out after the operation while it continues hot, and must be very carefully freed from the least remains of acid, otherwise it will be much corroded.

Copper-stills ought to be of as large a size as possible: but Dr Lewis very justly observes, that, in common ones, the width of the worm is by no means proportionable to the capacity of the still: hence the vapour which issues from a large surface being violently forced through a small tube, meets with so much resistance as sometimes to blow off the still-head. This inconvenience is ridiculously endeavoured to be prevented by strongly tying or otherwise forcing down the head; by which means, if the worm should happen to be choaked up, a terrible explosion would ensue: for no ligatures, or any other obstacle whatever, have yet been found strong enough to resist the elastic force of steam; and the greater obstacle it has to overcome, the greater would the explosion be.—Dangers of this kind might be totally avoided by having the worm of a proper degree of wideness.

Sometimes, however, matters are to be distilled, such as mineral acid spirits, which would corrode any kind of metalline vessels; and for these only earth, or the closest kind of stone-ware, can be used. These are more easily condensed than the steams of aqueous or vinous liquors, and therefore do not require to be passed through a pipe of such a length as is used for condensing the steams from the common still. In these cases, where a violent heat is not necessary, and the distillation is to be performed in glass vessels, the retort is used (fig. 4.) When a fluid is to be put into this vessel, the retort must be laid upon its back on sand, or any other soft matter that will support it with-

574

Mineral ac-
ids how
distilled.

576
Retort.

Chemical
Operations.Chemical
Operations.

without breaking. A funnel must also be procured with a long stem, and a little crooked at the extremity, that the liquor may pass at once into the belly of the retort, without touching any part of its neck; otherwise the quantity which adhered to the neck would pass into the receiver when the retort was placed in a proper situation for distilling, and foul the produce. When the vessel is properly filled, which ought never to be above two thirds, it is to be set in a sand bath; that is, in an iron pot, of a proper thickness, and covered over in the bottom, to the depth of one or two inches, with dry sand. When the retort is put in, so as to stand on its bottom, the pot is to be filled up with sand, as far as the neck of the retort. A glass receiver is then to be applied, which ought to be as large as possible, and likewise pretty strong; for which reason it will be proper not to let the capacity of it be above what is necessary to hold ten gallons. In the hinder part of it should be drilled a small hole, which may be occasionally shut by a small wooden peg. The mouth of the receiver ought to be so wide as to let the nose of the retort enter to the middle of it, or very near to it; for if the vapours are discharged very near the luting, they will act upon it much more strongly than when at a distance. It is likewise proper to have the neck of the retort as wide as may be; for this has a very great effect in the condensation, by presenting a larger surface to the condensing vapour.

577
Luting for
acid spirits.

The luting for acid spirits ought to be very different from that used in other distillations; for these will penetrate the common lutes so as to make them liquid and fall down into the receiver. Some have used retorts, the necks of which were ground to the receivers with emery; but these are very difficult to be procured, and are expensive, and consequently have never come into general use. Various kinds of lutes have been proposed, but the preference seems due to a mixture of clay and sand. We are not to understand, however, that every kind of clay is fit for this purpose: it must only be such as is not at all, or very little, affected by acids; and this quality is only possessed by that kind of which tobacco-pipes is made. Trial ought to be made of this before the distillation is begun, by pouring a little nitrous acid on the clay intended to be made use of. If a violent effervescence is raised, we may be sure that the clay is unfit for the purpose. Finely powdered alabaster would answer extremely well, had it the ductility of clay. As this kind of lute remains soft for a considerable time, it ought to be farther secured by a bit of rag spread with some strong cement, such as quicklime mixed with the white of an egg, &c. Matters, however, ought to be managed in such a manner, that the luting may give way, rather than the vessels burst; which would not only occasion a certain loss of the materials, but might endanger the persons who were standing by.

578
Balneum arenae.

The iron pots commonly used for distillations by the sand-bath, or *balneum arenae*, are commonly made very thick; and are to be sold at large founderies, under the name of *sand-pots*. The shape of these, however, is by no means eligible; for, as they are of a figure nearly cylindrical, if the retort is of such a size as almost to fill their cavity, it cannot be put into them

when full, and often pretty heavy, without great danger of touching the sides of the pot; and in this case, touching and *breaking* are synonymous expressions. It is much better, therefore, to have them in the figure of a punch-bowl; and the common cast-iron kettles, which may be had much cheaper than the sand-pots usually sold, answer extremely well. If the distilling vessel is placed in a pot filled with water, the distillation is said to be performed in a water-bath, or *balneum mariae*.

When the matter to be condensed is very volatile, a number of open receivers with two necks, called *adopters* (fig. 7.), may be used, with a close receiver at the end. Each of these adopters must be luted with as much care as when only a single receiver is made use of. Vessels of a similar kind were formerly much used by chemists for particular sublimations, under the name of *aludels*.

579
Adopters or
aludels.

Formerly, instead of retorts, a vessel called a *cucurbit*, (fig. 5, and 6.) with a head like the common still, called an *alembic*, were used; but the more simple figure of the retort gives it greatly the preference. It is but seldom that vessels of this kind are useful, which will be taken notice of when describing the particular operations: and if at any time an alembic head should be necessary, its use may be superseded by a crooked glass tube, which will answer the purpose equally well.

Sometimes a very violent fire is required in distillations by the retort. Here, where it is possible, glass or earthen vessels should be avoided, and iron pots substituted in their stead. The hardest and best cast iron, however, will at last melt by a vehement heat; and therefore there is a necessity for using earthen ware, or coated glass. This last is better than most kinds of earthen ware, as being less porous; for when the vessel is urged by a very intense heat, the glass melts, and forms a kind of semivitreous compound with the inside of the coating, so that its figure is still preserved, and the accidental cracks in the luting are filled up.

For coating of vessels, mixtures of colcothar of vitriol, sand, iron filings, blood, chopped hair, &c. have been recommended. We cannot help thinking, however, that the simple mixture of tobacco-pipe clay and sand is preferable to any other; especially if, as Dr Black directs, that part next the glass is mixed with charcoal dust.

580

Coating of
glasses.

The proportions recommended by the Doctor for luting the joints of vessels, are four parts of sand and one of clay; but for lining the insides of furnaces, and, we should think, likewise for coating glass vessels, he directs 6 or 7 of sand to 1 of clay; that the contraction of the clay in drying may thereby be the more effectually prevented. Besides this, he directs a mixture of three parts of charcoal-dust with one of clay to be put next the furnace itself, as being more apt to confine the heat; but possibly the first composition might be sufficient for glasses.

The coating of large glasses must be a very troublesome and tedious operation; and therefore coated glass is never used but in experiments. When large distillations are to be performed in the way of trade, recourse must be had either to iron pots, or to earthenware.

Chemical
Operations.

ware. Of the most proper kinds of earthen ware for resisting violent heats, we shall take notice under the article *Fusion*.

In all distillations by the retort, a considerable quantity of air, or other incondensable vapour, is extricated; and to this it is absolutely necessary to give vent, or the vessels would be burst, or the receiver thrown off. For this purpose, Dr Lewis recommends an open pipe to be inserted at the luting, of such an height as will not allow any of the vapour to escape; but this we cannot approve of, as by that means a constant communication is formed between the external atmosphere and the matters contained in the retort and receiver, which is at all times to be avoided as much as possible, and in some cases, as the distillation of phosphorus, would be very dangerous. The having a small hole drilled in the receiver, which is to be now and then opened, must answer the purpose much better, although it takes more attendance; but if the operator is obliged to leave the vessels for some time, it will be convenient either to leave the little hole open, or to contrive it so that the wooden peg may be pushed out with less force than is sufficient to break the lute.

581
Sublimation.

VII. *SUBLIMATION*. This, properly speaking, is only the distillation of a dry substance; and therefore, when volatile matters, such as salt of hartshorn, are to be sublimed, the operation is performed in a glass retort set in a sand bath, and the salt passes over into the receiver. The cucurbit and alembic were formerly much in use for this purpose; and a blind head, without any spout, was applied. A much simpler apparatus, however, is now made use of. A globe made of very thin glass, or an oblong vessel of the same kind, answers the more common purposes of sublimation. For experiments, Florence flasks are excellent; as being both very cheap, and having the necessary shape and thinness requisite for bearing the heat without cracking. The matter to be sublimed must not, on almost any occasion, take up more than a third part of the subliming vessel. It is to be set in a sand-bath, that the heat may be more equally applied than it could otherwise be. The heat must be no greater, or very little, than is necessary for sublimation, or it will be in danger of flying out at the mouth of the subliming vessel, or of choking it up so as to burst. The upper part of the vessel, too, must by no means be kept cool, but slightly covered with sand, that the matter may settle in a kind of half-melted state, and thus form a compact hard cake, which is the appearance sublimates are expected to have. Hence this operation requires a good deal of caution, and is not very easily performed.

582
Deflagration.

VIII. *DEFLAGRATION*. This operation is always performed by means of nitre, except in making the flowers of zinc. It requires open vessels of earth or iron; the latter are very apt to be corroded, and the former to imbibe part of the matter. To perform this process with safety, and without loss, the nitre ought to be mixed with whatever matter is to be deflagrated with it, and thrown by little and little into the vessel previously made red-hot. If much is put in at once, a great deal will be thrown out by the violent commotion; and to perform this operation in close vessels is in a manner impossible, from the prodigious quantity

of elastic vapour generated by the nitre. Care must also be taken to remove the whole mixture to some distance from the fire, and not to bring back any spark from the quantity deflagrating, with the spoon which puts it in; otherwise the whole would irremediably be consumed at once.

Chemical
Operations.

IX. *CALCINATION*. This is the subjecting any matter to a heat so violent as to dissipate some part of it, without melting what remains. It is often practised on metallic substances, particularly lead, for obtaining the calx of that metal called *minium*, or red lead.

583
Calcination.

This operation, as indeed all other chemical ones, is best performed in large quantities, where a particular furnace is constructed on purpose, and a fire kept on day and night without interruption. The flame is made to play over the surface of the metal, and it is continually stirred so as to expose different parcels of it to the action of the heat.

X. *FUSION*. This is when a solid body is exposed to such a degree of heat as makes it pass from a solid to a fluid state; and as different substances are possessed of very different degrees of fusibility, the degrees of melting heat are very various.

584
Fusion.

Besides the true fusion, there are some kinds of salts which retain so large a proportion of water in their crystals, as to become entirely fluid upon being exposed to a very small degree of heat. This is commonly called the *watery fusion*; but is really a *solution* of the salt in that quantity of water retained by it in its crystalline form: for such salts afterwards become solid by the evaporation of the water they contained; and then require a strong red heat to melt them thoroughly, or perhaps are absolutely infusible.

Of all known substances, unctuous and inflammable ones become fluid with the least heat; then come the more fusible metals, lead, tin, and antimony; then some of the more fusible salts; and then the harder metals, silver, gold, copper, and iron; then the mixtures for making glass; and last of all, the metal called *platina*, which has hitherto been incapable of fusion, except by the violent action of the sun-beams in the focus of a large burning glass. This substance seems to be the most refractory of all others, even the hardest flints melting into glass long before it. (See *PLATINA*.)

Fusion of small quantities of matter is usually performed in pots called *crucibles*; which, as they are required to stand a very violent heat, must be made of the most refractory materials possible.

The making of crucibles belongs properly to the potter: but as a *chemist* ought to be the judge of their composition, we shall here give some account of the different attempts to make these vessels of the necessary strength.

585
Crucibles,
proper materials for.

All earthen vessels are composed, at least partly, of that kind which is called the *argillaceous earth* or *clay*, because these only have the necessary ductility, and can be formed into vessels of the proper form. Pure clay is, by itself, absolutely unfusible; but is exceedingly apt to crack when exposed to sudden changes of heat and cold. It is also very apt to melt when mixed with other substances, such as calcareous earths, &c. When mixed in a certain proportion with other materials, they are changed by violent heat into

Chemical
Operations.

a kind of half-melted substance, such as our stone-bottles. They cannot be melted completely, however, by almost any fire; they are also very compact, and will contain the most fusible substances, even glass of lead itself; but as they are very apt to crack from sudden changes of heat and cold, they are not so much used; yet, on particular occasions, they are the only ones which can be made use of.

The more dense any kind of vessels are, the more apt they are, in general, to break by a sudden application of heat or cold: hence crucibles are not, in general, made of the greatest density possible; which is not at all times required. Those made at Hesse, in Germany, have had the best reputation for a long time. Mr Pott, member of the Academy of Sciences at Berlin, hath determined the composition of these crucibles to be, one part of good refractory clay, mixed with two parts of sand, of a middling fineness, from which the finest part has been sifted. By sifting the finer particles from the sand, too great compactness is avoided: but at the same time this mixture renders them apt to be corroded by vitrifying matters kept a long time in fusion; for these do not fail to act upon the sand contained in the composition of the crucible, and, forming a vitreous mass, at last run through it.

This inconvenience is prevented, by mixing, instead of sand, a good baked clay in gross powder. Of a composition of this kind are made the glass-house pots, which sometimes sustain the violent heat employed in making glass for several months. They are, however, gradually consumed by the glass, and become constantly more and more thin.

As the containing vessel, however, must always be exposed to a more violent heat than what is contained in it, crucibles ought to be formed of such materials as are not vitrifiable by the heat of any furnace whatever. But from the attempts made to melt platina, it appears, that of all known substances it would be the most desirable for a melting vessel. Hessian crucibles, glass-house pots, Sturbridge clay, in short every substance which could be thought of to resist the most violent heat, were melted in such a manner as even to stop up the pipes of large bellows, while platina was not altered in the least; and Messrs Macquer and Beaumé have shown, that though platina cannot be melted so as to cast vessels of it, it may nevertheless be cupelled with lead so as to become malleable, and thus vessels might otherwise be made from that substance. The extreme scarcity of this mineral, however, leaves as yet little room to hope for any thing from it, though Mr Achard has found a method of forming crucibles from this refractory substance. It consists in moulding the precipitate made with sal ammoniac into the form of a crucible, and then applying a sudden and very violent heat, which fuses this calx.

Mr Pott has made so many experiments upon clays mixed with different substances, that he has in a manner exhausted the subject. The basis of all his compositions was clay. This he mixed in different proportions with metallic calces, calcined bones, calcareous earths, talcs, amianthus, asbestos, pumice-stones, tripoli, and many others; but he did not obtain a perfect composition from any of them. The best crucibles, according to Scheffer, cannot easily contain metals dissolved by sulphur, in the operation of parting by means of sul-

phur. They may be made much more durable and solid, by steeping them a few days in linseed-oil, and strewing powdered borax upon them before they are dried.

The result of Mr Pott's experiments are: 1. Crucibles made of fat clays are more apt to crack when exposed to sudden heat, than those which are made of lean or meagre clays. *Meagre clays* are those which contain a considerable quantity of sand along with the pure argillaceous earth: and *fat clays* are those which contain but little. 2. Some crucibles become porous by long exposure to the fire, and imbibe part of the contained metals. This may be prevented, by glazing the internal and external surfaces; which is done by moistening these with oil of tartar, or by strewing upon them, when wetted with water, powdered glass of borax. These glazings are not capable of containing glass of lead. 3. Crucibles made of burnt clay grossly powdered, together with unburnt clay, were much less liable to crack by heat than crucibles made of the same materials where the burnt clay was finely powdered, or than crucibles made entirely of unburnt clay. 4. If the quantity of unburnt clay be too great, the crucible will be apt to crack in the fire. Crucibles made of 10 ounces of unburnt clay, 10 ounces of grossly powdered burnt clay, and three drachms of calcined vitriol, are capable of retaining melted metals, but are pervaded by glass of lead. The following composition is better than the preceding: Seven ounces of unburnt clay, 14 ounces of grossly powdered burnt clay, and one drachm of calx of vitriol. These crucibles may be rendered more capable of containing glass of lead, by lining their internal surfaces, before they are baked, with unburnt clay diluted with water. They may be further strengthened by making them thicker than is usually done; or by covering their external surfaces with some unburnt clay, which is called *arming* them. 5. The composition of crucibles most capable of containing the glass of lead, was 18 parts of grossly powdered burnt clay, as much unburnt clay, and one part of fusible spar. These crucibles must not, however, be exposed too suddenly to a violent heat. 6. Crucibles capable of containing glass of lead very well, were made of 24 parts of unburnt clay, four parts of burnt clay, and one part of chalk. These require to be armed. 7. Plume alum powdered, and mixed with whites of eggs and water, being applied to the internal surface of a Hessian crucible, enabled it to retain for a long time glass of lead in fusion. 8. One part of clay, and two parts of Spanish chalk, made very good crucibles. The substance called *Spanish chalk* is not a calcareous earth, but appears to be a kind of steatites. 9. Two parts of Spanish chalk, and one part of powdered tobacco-pipes, made good lining for common crucibles. 10. Eight parts of Spanish chalk, as much burnt clay, and one part of litharge, made solid crucibles. 11. Crucibles made of black lead are fitter than Hessian crucibles for melting metals; but they are so porous, that fused salts pass entirely through them. They are more tenacious than Hessian crucibles, are not so apt to burst in pieces, and are more durable. 12. Crucibles placed with their bottoms upwards, are less apt to be cracked during the baking, than when placed differently. 13. The paste of which crucibles are made, ought not to be too moist;

moist; else, when dried and baked, they will not be sufficiently compact: hence they ought not to be so moist as to be capable of being turned on a potter's lathe; but they must be formed in brass or wooden moulds.

On this subject Dr Lewis hath also made several observations; the principal of which are, 1. Pure clay softened to a due consistence for being worked, not only coheres together, but sticks to the hands. In drying, it contracts 1 inch or more in 12; and hence it is very apt to crack, unless it is dried exceeding slowly. In burning, it is subject to the same inconvenience, unless very slowly and gradually heated. When thoroughly burnt, if it has escaped those imperfections, it proves solid and compact; and so hard as to strike fire with steel. Vessels made of it are not penetrated by any kind of liquid; and resist salts and glasses brought into the thinnest fusion, excepting those which by degrees corrode and dissolve the earth itself, as glass of lead; and even this penetrating glass is resisted by it better than by almost any other earth; but, in counterbalance to these good qualities, they cannot be heated or cooled, but with such precautions as can rarely be complied with in the way of business, without cracking, or flying in pieces.

2. Clay that has been once exposed to any considerable degrees of heat, and then powdered, has no longer any tenacity. Fresh clay, divided by a due proportion of this powder, proves less tenacious than by itself; not sticking to the hands, though cohering sufficiently together. It shrinks less in drying, is less apt to crack, and less susceptible of injury from alterations of heat and cold; but at the same time is less solid and compact. Considerable differences are observed in these respects; not only according to the quantity of dividing matter, but according as it is in finer or coarser powder.

3. Vessels made with a moderate proportion of fine powder, as half the weight of the clay, are compact and solid, but still very apt to crack, from sudden heat or cold: those with a larger proportion, as twice or thrice the quantity of the clay, are free from that imperfection, but so friable as to crumble between the fingers. Nor does there appear to be any medium between a disposition to crack and to crumble; all the compounds made of clay and fine powders having the one or the other, or both imperfections. Coarser powders of the size of middling sand, form, with an equal weight of clay, compounds sufficiently solid, and much less apt to crack than the mixtures with fine powders. Two parts of coarse powder, and one of clay, prove moderately solid, and but little disposed to crack: a mixture of three parts and one, tho' heated and cooled suddenly, does not crack at all, but suffers very fluid substances to transude through it; solidity, and resistance to quick vicissitudes of heat and cold, seeming here also to be incompatible.

4. Pure clay, mixed with pure clay that has been burnt, is no other than one simple earth; and is neither to be melted nor softened, nor made in any degree transparent with the most intense fires.

5. Mixtures of clay with gypseous earths burn whiter than clay alone; in certain proportions, as two parts of clay to three of gypsum, they become, in a

moderate fire, semi-transparent, and in a strong one they melt.

6. Calcareous earths in small proportion bake tolerably compact and white; and added to other compositions, seem to improve their compactness. If the quantity of the calcareous earth nearly equals that of the clay, the mixture melts into a yellow glass; if it considerably exceeds, the product acquires the qualities of quicklime.

7. Vessels made from clay and sand, in whatever proportion, do not melt in the strongest fire; but they sometimes bend or soften, so as to yield to the tongs. Glasses in thin fusion penetrate them by dissolving the sand. If gypseous or calcareous earths are urged in such crucibles with a vehement heat, the vessels and their contents run all into one mass. In moderate fires, these vessels prove tolerably compact, and retain most kinds of salts in fusion; but they are liable to crack, especially when large; and do not long sustain melted metals, being burst by their weight. Such are the Hessian crucibles.

8. Mixtures of clay and black-lead, which seems a species of talc, are not liable to crack from alternations of heat and cold; but are extremely porous. Hence black-lead crucibles answer excellently for the melting of metals, and stand repeated fusions; whilst salts flowing thin, transude through them almost as water through a sieve: sulphureous bodies, as antimony, corrode them.

9. Pure clay, softened with water, and incrustated on earthen vessels, that have been burnt, does not adhere to them, or scales off again upon exposure to the fire; applied to unburnt vessels, it adheres and incorporates. Divided clay unites with them in both states. Vitreous matters, melted in vessels of pure clay, adhere so firmly as not to be separated; from vessels of divided clay they may be knocked off by a hammer.

10. The saline fluxes which promote the fusion of clay, besides the common ones of all earths, alkali and borax, are chiefly arsenic fixed by nitre, and the fusible salt of urine; both which have little effect on the other earths though mixed in a large proportion. Nitre, which readily brings the crystalline earths into fusion, and sal mirabile and sandiver, powerful fluxes for the calcareous earths, do not perfectly vitrify with clay. Burnt clay does not differ in these respects from such as has not been burnt; nor in that singular property of vitrifying with gypseous or calcareous earths, without any saline or metallic addition; the utmost vehemence of fire seeming to destroy only its ductility, or that power by which it coheres when its parts are moistened with water.

But though it seems impossible to make perfect vessels from mixtures of clay in its two different states, of burnt and unburnt, more is to be hoped from the mixtures which are employed in making porcelain. Manufactories of this kind of ware have been attempted in different countries, (see PORCELAIN); and in some places the qualities requisite for chemical vessels have been given to it in a very surprising degree. The count de Lauraguais, a French nobleman, and member of the academy of sciences, has distinguished himself in a very eminent manner by attempts of this kind. The

Mr Reau-
mur's por-
celain.

translator of the chemical dictionary assures us, that he had it from a gentleman of undoubted veracity, that this nobleman having heated a piece of his porcelain red hot, threw it into cold water, without breaking or cracking it.

The most useful attempt, however, for the purposes of chemistry, seems to be the discovery by Mr Reaumur of converting common green glass into porcelain. This was published as long ago as the year 1739; yet we have scarce heard of any chemist, no not Dr Lewis himself, who has made trial of chemical vessels formed of this sort of porcelain, although the very use to which Mr Reaumur thought the preparation could be applicable was that of bringing chemical vessels to a degree of perfection which could not otherwise be done. The following is the result of Mr Reaumur's experiments.

Green glass, surrounded with white earthy matters, as white sand, gypsum, or plaster of Paris, &c. and exposed to a considerable heat not strong enough to alter its figure, as that of a potter's furnace, acquires different shades of blue, and by degrees begins to grow white. On breaking the glass, the white coat appears to be composed of fine, white, glossy, satin-like fibres, running transversely, and parallel to one another; the glass in the middle being scarcely altered. On continuing the cementation, the change proceeds further and further, till at length the white fibrous parts from both sides meet in the middle, and no appearance of glass remains. By this means, entire vessels of glass may be changed into porcelain.

The substance into which glass is thus converted, is opaque, compact, internally of great whiteness, equal to that of the finest china-ware; but, externally, of a much duller hue. It is considerably harder than glass, much less fusible in the fire, and sustains alterations of heat and cold without injury. Vessels of it, cold, bear boiling liquors; and may be placed on the fire at once, without danger of their cracking. "I have put a vessel of this porcelain (says the author) into a forge, surrounded it with coals, and kept vehemently blowing for near a quarter of an hour; I have melted glass in this vessel, without its having suffered any injury in its figure." If means could be found of giving the outside a whiteness equal to the internal part, glass vessels might thus be converted into a valuable kind of porcelain, superior to all that have hitherto been made. Chemistry, says he, may receive from this discovery, in its present state, such vessels as have been long wanted; vessels which, with the compactness and impenetrability of glass, are also free from its inconveniences.

The common green glass bottles yield a porcelain of tolerable beauty; window-glasses, and drinking-glasses, a much inferior one; while the finer kinds of crystalline glasses afforded none at all. With regard to the cementing materials, he found white sand and gypsum, or rather a mixture of both, to answer best. Coloured earths generally make the external surface of a deeper or lighter brown colour; foot and charcoal, of a deep black, the internal part being always white.

593
Dr Lewis's
experi-
ments.

The account of this kind of porcelain given by Mr Reaumur, induced Dr Lewis, who had also observed the same changes on the bottom of glass-retorts ex-

posed to violent heat in a sand-bath, to make further experiments on this matter; an account of which he has published in his *Philosophical Commerce of Arts*. The results of his experiments were, 1. Green glass, cemented with white sand, received no change in a heat below ignition. 2. In a low red heat, the change proceeded exceeding slowly; and in a strong red heat, approaching to white, the thickest pieces of glass bottles were thoroughly converted in the space of three hours. 3. By continued heat, the glass suffered the following progressive changes: first, its surface became blue, its transparency was diminished, and a yellowish hue was observable when it was held between the eye and the light. Afterwards it was changed a little way on both sides into a white substance, externally still bluish; and, as this change advanced still further and further within the glass, the colour of the vitreous part in the middle approached nearer to yellow: the white coat was of a fine fibrous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickness of the piece: by degrees the glass became white and fibrous throughout, the external bluishness at the same time going off, and being succeeded by a dull whitish or dun colour. By a still longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture was then not unlike that of common porcelain. The grains, at first fine and somewhat glossy, became by degrees larger and duller; and at last the substance of the glass became porous and friable, like a mass of white sand slightly cohering. 4. Concerning the qualities of this kind of porcelain, Dr Lewis observes, that, while it remained in the fibrous state, it was harder than common glass, and more able to resist the changes of heat and cold than glass, or even porcelain; but, in a moderate white heat, was fusible into a substance not fibrous, but vitreous and smooth, like white enamel: that when its texture had become coarsely granulated, it was now much softer and unfusible: and lastly, that when some coarsely granulated unfusible pieces, which, with the continuance of a moderate heat, would have become porous and friable, were suddenly exposed to an intense fire, they were rendered remarkably more compact than before; the solidity of some of them being superior to that of any other ware.

It seems surprising that this able chemist, who on other occasions had the improvements of the arts so much at heart, did not put some vessels of this kind of porcelain to other severe trials, besides attempting to fuse it by itself with a violent fire: for though pieces of it were absolutely unfusible, we are not sure but they might have been corroded by alkaline salts, acids, calcareous earths, or glass of lead; nay, it should seem very probable that they would have been so: in which case they would not be much superior to the vessels made from earthy materials. When a first-rate chemist publishes any thing in an imperfect state, inferior ones are discouraged from attempting to finish what he has begun; and thus, notwithstanding that these experiments have been so long published, nobody has yet attempted to investigate the properties of this kind of porcelain, by getting chemical vessels made of it, and trying how they answer for crucibles, or retorts.

594
This sub-
ject still
imperfect.

Chemical
Operations.

All that has been said concerning the proper materials for crucibles, must likewise be applicable to the materials for retorts, which are required to stand a very violent heat. Mr Reaumur's porcelain bids fairest for answering the purpose of retorts, as well as crucibles. The great disadvantage of the common earthen ones, is, that they suffer a quantity of volatile and penetrating vapours to pass through them. This is very observable in the distillation of phosphorus; and though this substance has not hitherto been used for any purpose in medicine, and very little in the arts, its acid only being sometimes used as a flux, if vessels could be made capable of confining all the steams, and at the same time bearing the heat necessary for its distillation, phosphorus, perhaps, might be obtained in such quantity, as to show that it is a preparation not altogether useless.

595 [596]
Stone-ware
vessels cor-
roded.

With regard to stone-ware vessels, and all those in which the composition of sand or flint enters, we shall only further observe, that they will be corroded by fixed alkaline salts, especially of the caustic kind, in a very moderate heat. Dr Black, having evaporated some caustic ley in a stone-ware basin, and then melted the dry salt in the same vessel, found it so corroded, as afterwards to be full of small holes; and he found nothing to resist the action of this salt so well as silver. On the subject of chemical vessels, we have now, however, to add the improved earthen ware of Mr Wedgewood; in which the properties of compactness, infusibility, and the power of resisting sudden changes of heat and cold, are said to be united, so that it promises to be a very valuable addition to the chemical apparatus.

597
Wedge-
wood's
ware.598
Maceration.

II. MACERATION, OR DIGESTION. This is the mixing two bodies, generally a solid and a fluid, together, and then exposing them to a moderate degree of heat for a considerable length of time, that so they may have the better opportunity of acting upon one another. Digestion is usually performed in the glasses already mentioned, called *matrasses* or *bolt-heads*; and is done in a sand heat. When any of the substances are very volatile, as spirit of wine; or when the matter requires to be heated so considerably that a quantity of vapour will be raised, the necks of the bolt-heads ought to be pretty long; or a tin pipe may be inserted, of sufficient length to prevent the escape of any part of the steam.

599
Levigation.

12. LEVIGATION. This is the reducing any body to a very fine powder, which shall feel quite soft between the fingers or when put into the mouth. It is performed by grinding the substance upon a flat marble stone, with some water, or by rubbing it in a marble mortar. In the large way, levigation is performed by mills drawn by horses, or driven by water; some of them are so small as to be turned by the hand. They consist of two smooth stones, generally of black marble, or some other stone equally hard, having several grooves in each, but made to run in contrary directions to one another when the mill is set in motion. The matter being mixed with water, is put in by a funnel, which is fixed into a hole in the upper stone, and turns along with it. The under millstone has round it a wooden ledge, whereby the levigating matter is confined for some time, and at length dis-

charged, by an opening made for that purpose, when it has accumulated in a certain quantity.

Chemical
Furnaces.

In this operation, when the matters to be levigated are very hard, they wear off a part of the mortar, or stones on which they are levigated; so that a substance perfectly hard, and which could not be worn by any attrition, is as great a desideratum for the purposes of levigation, as one which could not be melted is for those of fusion. Dr Lewis proposes the porcelain of Mr Reaumur as an improvement for levigating planes, mortars, &c. because, while in its fibrous state, it is considerably harder than glass, and consequently much less liable to abrasion by the harder powders.

In many cases levigation is very much accelerated by what is called *elutriation*. This is the method by which many of the painters colours are prepared of the requisite fineness; and is performed by mixing any substance, not totally reduced to the necessary degree of fineness, with a sufficient quantity of water, and stirring them well together. The finer parts of the powder remain some time suspended in the water, while the grosser particles fall to the bottom. The separation is then easily made, by pouring off the water impregnated with these fine parts, and committing the rest to the levigating mill, when it may again be washed; and this may be repeated till all the powder is reduced to the utmost fineness. Substances soluble in water cannot be levigated in this manner.

OF CHEMICAL FURNACES.

THE two general divisions we have already mentioned of those who practise chemistry, namely, those who have no other view than mere experiment, and those who wish to profit by it, render very different kinds of furnaces necessary. For the first, those furnaces are necessary which are capable of acting upon a small quantity of matter, yet sufficient for all the changes which fire can produce, from simple digestion to the most perfect vitrification. For the others, those are to be chosen which can produce the same changes upon very large quantities of matter, that as much may be done at once as possible.

To avoid the trouble and expence of a number of furnaces, a portable one hath long been a desideratum among those chemists who are fond of making experiments. One of the best of those, if not the very best, that hath yet appeared, is that described in Shaw's edition of Boerhaave's chemistry, and represented fig. 1.

600

Portable
furnace.

This furnace is made of earth; and, as the workmanship of a furnace requires none of the neatness or elegance which is required in making potters vessels, any person may easily make a furnace of this kind for himself, who has time and patience for so doing. With regard to the most proper materials, all that we have said concerning crucibles and retorts must be applicable to the materials for constructing a furnace; only here we need not care so much for the porosity, or disposition to crumble, as when crucibles or other distilling vessels are to be made.

Plate-iron is commonly directed for the outside of portable furnaces; but we cannot help thinking this is a very needless expence, seeing the coating which

Plate
CXXXIV.

it

Chemical
Furnaces.

it necessarily requires on the inside may be supposed to harden to such a degree as soon to support itself, without any assistance from the plate-iron. This will be the less necessary, if we consider, that, for the thickness of the walls of any furnace where a considerable heat is wanted, two or three inches are by no means sufficient. When the inside of a furnace is heated, the walls, if very thin, are soon penetrated by the heat, and great part of it by this means dissipated in the air. If they are of a sufficient thickness, the heat cannot penetrate so easily; and thus the inner part of the furnace preserves the heat of the fuel, and communicates it to the contained vessel. In the construction of a portable furnace, therefore, it will be convenient to have all parts of it six inches thick at least. This will also give it a sufficient degree of strength; and, as it is formed of several different pieces, no inconvenience can follow from the weight of each of them taken separately.

In Boerhaave's chemistry, this furnace is represented as narrower at the bottom than at the top; but we cannot suppose any good reason for such a form, seeing a cylindrical one must answer every purpose much better, as allowing a larger quantity of air to pass through the fuel, and likewise not being so apt to be overturned as it necessarily must be where the upper part is considerably heavier than the lower. We have, therefore, given a representation of it as of a cylindrical form.

The furnace consists of five or more parts. C, represents the dome, or top of the furnace, with a short earthen funnel E for transmitting the smoke. B, B, B, are moveable cylinders of earth, each provided with a door D, D, D. In Boerhaave's chemistry these doors are represented as having iron hinges and latches; but they may be formed to more advantage of square pieces of earth, having two holes in the middle, by which they may be occasionally taken out, by introducing an iron fork. In like manner, the domes and cylinders, in Boerhaave's chemistry, are represented with iron handles; but they may be almost as easily taken off by the cheaper contrivance of having four holes in each, two directly opposite to one another, into which two short forks may be introduced when the parts are to be separated.

In the lowermost cylinder is to be placed an iron-grate, a little below the door, for supporting the fire. In the under part is a small hole, big enough for introducing the pipe of a pair of good perpetual bellows, when the fire is to be violently excited. Dr Lewis prefers the organ-bellows to any other kind.

When the bellows is used, the whole must stand upon a close cylinder A, that the air may be confined, and made to pass through the fuel. By having more bellows, the fire may be excited to a most intense degree. In this case, the pipe of every one of them must enter the cylinder B.

Each of the cylinders should have, in its upper part, a round hole, opposite to its door, for carrying off the smoke, by means of a pipe inserted into it, when the furnace is used for distillations by the sand-bath. Each cylinder ought likewise to have a semicircular cut in the opposite sides, both above and below, that when the under cut of the upper cylinder is brought directly above the upper cut of the lower one, a per-

fect circle may be formed. These are for giving a passage to the necks of retorts, when distillation by the retort is to be performed. The holes may be occasionally filled with stopples made of the same materials with the body of the furnace.

The most convenient situation for a furnace of this kind would be under a chimney; the vent of which might be easily stopped up by a broad plate of iron, in which a hole ought to be cut for the reception of the earthen tube of the dome. By this means the use of a long tube, which at any rate must be very troublesome, might be easily avoided, and a very strong blast of air would pass through the fuel. If it is found convenient to place the furnace at some distance from the chimney, a plate-iron pipe must be procured to fit the earthen pipe of the dome, and carry the smoke into the chimney. This pipe will also be of use, when the furnace is used for distillations by the sand-bath; it must then be inserted into the hole opposite to the door of any of the cylinders, and will convey away the smoke, while the mouth of the cylinder is totally covered with a sand-pot.

For portable furnaces, Dr Lewis greatly recommends the large black crucibles, marked n° 60, on account of their resisting a violent heat, and being very easily cut by a knife or saw, so that doors, &c. may be formed in them at pleasure. The bottom of one of these large ones being cut out, a grate is to be put into the narrow part of it. For grates, the doctor recommends cast-iron rings, having each three knobs around them. These knobs go into corresponding cavities of the outer rings, and the knobs of the outermost rest on the crucible, which is to be indented a little to receive them, that so the grate may rest the more firmly, and the furnace not be endangered from the swelling of the iron by heat. When this is to be made use of as a melting-furnace, and a violent heat to be excited, another crucible must be inverted on that which contains the fuel, which serves instead of the dome of the last mentioned furnace: and as whatever is said of it must likewise be applicable to the two crucibles when placed above one another, we need give no farther description of the doctor's portable furnace.

No doubt, the great experience of Dr Lewis in chemical matters must give very considerable weight to any thing he advances; and the warmth with which he recommends these furnaces must convince us, that he has found them abundantly answer the purposes of experiments. We cannot help thinking, however, that where a very great and lasting heat is to be given, the thinness, and even the *form*, of these crucibles, is some objection to their use. It is certain that such a permanent, or, as the workmen call it, a *solid* heat, can never be given where the walls of a furnace are thin, as when they are of sufficient thickness. They are also very apt to burst with great heat; and, for this reason, Dr Lewis desires his furnace to be strengthened with copper hoops. This disposition to burst proceeds from the inner parts, which are more intensely heated than the outer, expanding more than these do, and consequently bursting them. Hence the doctor desires his furnace to be strengthened also by putting it within another crucible of a larger size, and the intermediate space to be filled up with a mixture

ture of sifted ashes and water. For most chemical processes, where only a small degree of heat is requisite, these furnaces answer beyond any thing that has hitherto been attempted. The whole is to be supported by an iron ring with three feet.

2d 602
Dr Black's
furnace de-
scribed.

Dr Black has contrived a furnace in which all these inconveniences are avoided. Two thick iron plates, above and below, are joined by a thinner plate, forming the body of the furnace, which is of an oval form. The upper part is perforated with two holes; the one, A, pretty large, which is the mouth of the furnace, and which is of a circular form; the other behind it, B, of an oval form, and designed for fastening the end of the vent which is screwed down upon it. The undermost thick plate has only one large circular opening G near to the middle, but not altogether so, being nearer to one side of the ellipse than the other, where the round hole in the top is placed; so that a line passing this circular hole has a little obliquity forwards. The ash-pit HH is likewise made of an elliptical form, and a very small matter widened; so that the bottom of the furnace is received within the ellipse. A little below, there is a border E that receives the bottom of the furnace; and except the holes of the damping-plate DD, the parts are all closed by means of soft lute, upon which the body of the furnace is pressed down; by which means the joining of the two parts, and of all the different pieces, are made quite tight; for the body, fire-place, ash-pit, vent, and grate, are all separable from one another. As the furnace comes from the workman, the grate is made to apply to the outside of the lower part. It consists of a ring laid on its edge, and then bars likewise laid on their edges: and from the outer ring proceed four pieces of iron, by means of which it may be screwed down; so it is kept out of the cavity of the furnace, and preserved from the extremity of the heat. Thus it lasts much longer, and is indeed hardly liable to any decay; for by being exposed to the cool air, it is kept so cool, that it is never hurt by the heat of the fuel. The sides, which are made of plate iron, must be luted within, to confine the heat, and preserve them from its action.

603
How adapted to the
various operations
of chemistry.

To adapt this to the various operations of chemistry, we may observe, that for a melting furnace it is very convenient; we need only provide a cover for the opening above, which is made the door; and which, being immediately over the grate, is convenient for introducing the substances to be acted upon, and for allowing us to look into the vessel and take it out. This cover may be a piece of tile, or two bricks rendered flat and square. Dr Black commonly uses a kind of lid with a rim containing a quantity of lute; and to augment the heat, we may increase the height of the vent. It can be employed in most operations in the way of assaying; and the situation of the door allows us to see the substances very readily. It does not admit the introduction of the muffle; but can be employed in all those operations where the muffle is made use of; and in Cornwall in England such a furnace is made use of for assaying of metals. To preserve the substance from the contact of the fuel, they cut off about a third part of the length of a brick, and then put it on one end on the middle of the grate. They choose their fuel of large pieces, that the air may have free passage through it, and open a little of

the door, which occasions a stream of air to flow in; and this strikes upon the substance and produces the effect desired: so that it may be used in the calcination of lead to convert it into litharge. It also answers very well in operations for producing vapour. If we desire to employ it in distillations which require an intense heat, the earthen retort is to be suspended by means of an iron ring having three branches standing up from it, and which hangs down about half a foot from the hole; so that the bottom of the retort rests upon the ring, and is immediately hung over the fuel: and the opening between the mouth of the furnace and retort is filled up with broken crucibles and potsherds, which are covered over with ashes that transmit the heat very slowly; so it answers for distillations performed with the naked fire. Dr Black has sometimes caused them be provided with a hole in the side, from which the neck of the retort may be made to come out; and in this way has distilled the phosphorus of urine, which requires a very strong heat. For distillations with retorts performed with the sand-bath, there is an iron pot fitted for the opening of the furnace, which is set on and employed as a sand-pot. The vent of the furnace then becomes the door; and it answers very well for that purpose; and is more easily kept tight than if it were in the side, and may be kept close with a lid of charcoal and clay. In like manner it answers well for the common still, which may be adapted to it; part of it being made to enter the open part of the furnace, and hang over the fire, as in Plate CXXXIII. fig. 7. and 8. that the bottom part of that still may be made to enter; and the vent becomes the door, by which fresh fuel may be added. Indeed it is seldom necessary to add fresh fuel during any operation. In the ordinary distillations it is never necessary; and even in distilling mercury, phosphorus, &c. it generally contains enough to finish the operation; so effectually is the heat preserved from loss or dissipation, and so very slow is the consumption of the fuel.

For luting this and other furnaces, the doctor finds nothing preferable to a simple mixture of sand and clay. The proportions for standing the violence of fire are four parts of sand to one of clay; but when designed for the lining of furnaces, he uses six or seven of sand to one of clay, the more effectually to prevent the contraction of the latter; for it is known from experiments, that clay, when exposed to a strong heat, contracts the more in proportion to its purity. The sand settles into less bulk when wet, and does not contract by heat, which it also resists as well as the clay itself.

Besides this outside lining next the fire, Dr Black uses another to be laid on next the iron of the furnace; and this consists of clay mixed with a large proportion of charcoal dust. It is more fit for containing the heat, and is put next to the iron, to the thickness of an inch and a half. That it may be pretty dry when first put in, he takes three parts by weight of the charcoal dust, and one of the common clay, which must be mixed together when in dry powder, otherwise it is very difficult to mix them perfectly. As much water is added as will form the matter into balls; and these are beat very firm and compact by means of a hammer upon the inside of the furnace. The other lute is then spread over it to the thickness of about half

604

applying
the lute.

Chemical
Furnaces.Chemical
Furnaces.

an inch, and this is also beat solid by hammering; after which it is allowed to dry slowly, that all cracks and fissures may be avoided: and after the body of the furnace is thus lined, the vent is screwed on and lined in the same manner. It must then be allowed to dry for a long time; after which a fire may be kindled, and the furnace gradually heated for a day or two. The fire is then to be raised to the greatest intensity; and thus the luting acquires a hardness equal to that of free-stone, and is afterwards as lasting as any part of the furnace (A).

2d 605
Melting
furnace.

When furnaces are used in the large way, they are always built of brick, and each particular operation has a furnace allotted for itself. The melting-furnace, where very large quantities of matter are not to be melted at once, requires only to be built of brick in such a form as we have already described; only, as it would perhaps be troublesome to procure a dome of the proper figure, the forepart of it may be left entirely open for the admission of melting vessels. The opening may be closed up with bricks and earth during the operation. There is no necessity for having the inside of a circular form; a square one will answer the purpose equally well. According to the author of the Chemical Dictionary, when the internal diameter D C of such a furnace is 12 or 15 inches, the diameter of the tube G I 8 or 9 inches, and its height 18 or 20 feet, and when the furnace is well supplied with fuel, an extreme heat is produced; in less than an hour the furnace will be white and dazzling like the sun; its heat will be equal to the strongest glass-house furnace; and in less than two hours will be melted whatever is fusible in furnaces. The hottest part is at H F, 4 or 6 inches above the grate. A plate-iron tube may be advantageously supplied by a short chimney of bricks, built under a pretty high vent, so as the whole may easily be stopped, except that passage which transmits the smoke of the furnace. By this means a very strong current of air will be made to pass through the fuel.

Plate
CXXXIV.
fig. 2.606
Mr Pott's
melting
furnace de-
scribed.

On this subject Dr Black informs us, that Mr Pott of Berlin employs one almost similar to the above, for making experiments on earthen ware; by which he showed that many substances formerly reckoned infusible, might nevertheless be melted by fire raised to a very intense degree; and that several of these bodies, when mixed together, form compounds which may be melted without any difficulty. From this a tube arises to some height, and there is an additional tube which may be put on to the height of above 10 feet. The fire-place is narrow below, but widens towards the middle, and contracts again at top, for the sake of the vessels which are put into it, and which are wider at top than at bottom. Thus the vessel is equally heated, and there is room above for containing a quantity of fuel, which descends as fast as it is consumed. Different reasons have been assigned for this form: thus Dr Boerhaave imagines that the melting furnace should be made of a parabolic form, and Macquer that it should be in the form of an ellipse; and that the crucible should be placed in one of the foci, where they

imagined the heat would be concentrated; but it is very plain, that the materials are such as are not capable of reflecting the rays of heat in a regular manner; and even though they could do so, it would be to no purpose, because the heat and light do not come from any single point, but from a great number, striking the furnace in all possible directions, and which must consequently be reflected in directions as numerous. The furnace is made of iron lined with clay; and as it is difficult to beat out the iron into this roundish form, it may as well be made cylindrical; and it is easy to give the inside what form we please by means of a luting of clay; neither need the dome have the roundish form, but may be simply made conical. The vent should be made about two-thirds of the diameter of the furnace, or such as will give an area of about one-half the grate. A small portable furnace of this kind is very convenient for ordinary crucibles; the largest of which are only about four or five inches high; the widest part of the furnace may be beat out about 10 inches diameter; and when made of thin plate iron, and lined within, are very convenient, and may be heated at very little expence of fuel. But for heating much larger vessels, it is proper to construct them of brick, when they have pretty much the same form; only it is necessary to make them square, and round on the inside with a luting of sand and clay. The top is generally made flat, and covered over with two or three bricks; the vent goes a little backwards, and then is raised to a proper height. Where the vessel to be heated is very large, it is common to leave the front open for putting in the vessel; and then to build it up with bricks, clay, and sand; which can be easily pulled down again when the operation is over.

There are some cases in which it is necessary to have a rapidity of inflammation even beyond what this furnace can give; and in these we have recourse to bellows of various constructions, by which the air can be compressed, and made to enter the fuel with great velocity. These again are sometimes wrought by water; but there is another machine which produces a greater effect, viz. the *water-blast*, described by Lewis in his *Commercium Philosoph. Technicum*.

The eolipile too may be employed for driving air in to fuel. The effect of this has been considered as a proof that air acts by its elasticity in animating fuel, as an elastic fluid vapour from the eolipile produces the same effect. But when we contrive to send steam instead of air, the same effect is not produced; and the true manner in which this instrument increases the inflammation is by driving air through the fuel; the steam from the vessel spreading and mixing with the air, and driving it before it, makes it strike upon the fuel.

Chemists have generally believed that a wide and high ash-hole greatly increases the power of a melting furnace; but this advantage is found to be merely imaginary, as well as that of introducing the air through a long tube to the ash-hole; unless where the furnace is placed in a close room, so that it is necessary to furnish a greater blast of air than can otherwise have access.

For

(A) These furnaces, of different sizes, from 30s. to 50s. price, may be purchased from John Sibbald smith in Edinburgh; who has had the advantage of making them under the immediate inspection of Dr Black.

Chemical
Furnaces.610
Stills, sand-
pots, &c.
how to set.

For the form of the furnaces necessary in assaying and smelting of ores or making glass, see ESSAYING, GLASS, and SMELTING.

When large stills, sand-pots, &c. are to be fixed with a view to daily use, it is a matter of no small consequence to have them put up in a proper manner. The requisites here are, 1. That the whole force of the fire should be spent on the distilling vessel or sand-pot, except what is necessarily imbibed by the walls of the furnace. 2. That the vessel should be set in such a manner as that they may receive heat even from the furnace walls; for a still which contains any liquid can never be made so hot as a piece of dry brick. 3. It is absolutely necessary that the force of the fire be not allowed to collect itself upon one particular part of the vessel; otherwise that part will soon be destroyed. 4. The draught of air into furnaces of this kind ought to be moderate; only so much as will prevent smoke. If a strong blast of air enters, not only a great part of the heat will be wasted by going up the chimney, but the outside of the vessel will be calcined every time the fire is kindled, and thus must be soon rendered unfit for use.

There are few of the common workmen that are capable of building furnaces properly; and it is very necessary for a chemist to know when they are properly done, and to make the workmen act according to his directions. As the still, or whatever vessel is to be fixed, must have a support from the furnace on which it is built, it is evident the whole of its surface cannot be exposed to the fire. For this reason many of these vessels have had only their bottom exposed to the fire, no more space being left for the action of the heat, than the mere circular area of the still bottom; and the fire, passing directly through a hole in the back part of the building, which communicated with a chimney, and consequently had a strong draught, scarce spent any of its force on the still, but went furiously up the chimney. By this means an extraordinary waste of fuel was occasioned; and that part of the still-bottom which was next the chimney receiving the whole force of the flame, was soon destroyed. Attempts were made to remedy this inconvenience, by putting the fire something forward, that it might be at a greater distance from the chimney, and consequently might not spend its force in the air. This too was found to avail very little. A contrivance was then fallen upon to make the vent pass round the body of the still in a spiral form. This was a considerable improvement; but had the inconvenience of making the fire spend itself uselessly on the walls of the furnace, and besides wasted that part of the still which touched the under part of the vent. A much better method is to build the back part of the furnace entirely close, and make the fire come out through a long narrow opening before; after which it passes out through a flue in the back and upper part of the furnace into the chimney.

The only inconvenience of this form is, that the vent must either be very wide, or it is apt to choak up with soot, which last is a very troublesome circumstance. If the vent is made very wide, a prodigious draught of air rushes through the fuel, and increases the heat to such a degree as to calcine the metal of which the still is made; and, on the other hand, no-

thing can be more disagreeable than to have the vent of a furnace stopped up with soot. These inconveniences, however, are totally avoided by making two small vents, one on each side of the distilling vessel, which may communicate with a chimney by means of two tubes either of plate-iron or formed with clay or bricks, which may be occasionally taken off if they happen to be choaked up. The vessel is to be supported by three trunnions, so that the whole surface may be exposed to the fire, excepting a ring the thickness of a brick all round; so that a very strong heat will be communicated although the furnace draws but little. The two small vents on each side will draw the flame equally; and by this means the most equable heat can be preserved, and may be pushed so far as to make the whole bottom and sides of the vessel intensely red. Such a construction as this is more especially useful for sand-pots, and those which are used for distilling alkaline spirits from bones.

In the use of the furnaces hitherto described, the attendance of the operator is necessary, both for inspecting the processes, and for supplying and animating the fuel. There are some operations, of a slower kind, that require a gentle heat to be continued for a length of time; which demand little attendance in regard to the operations themselves, and in which, of consequence, it is extremely convenient to have the attendance in regard to the fire as much as possible dispensed with. This end has been answered by the furnace called *athanor*; but the use of it has been found attended with some inconveniences, and it is now generally laid aside.

Sundry attempts have been made for keeping up a continued heat, with as little trouble as in the *athanor*, by the flame of a lamp; but the common lamp-furnaces have not answered so well as could be wished. The lamps require frequent snuffing, and smoke much; and the soot accumulated on the bottom of the vessel placed over them, is apt, at times, to fall down and put out the flame. The largeness of the wick, the irregular supply of oil from the reservoir by jets, and the oil being suffered to sink considerably in the lamp, so that the upper part of the wick burns to a coal, appeared to be the principal causes of these inconveniences; which accordingly were found to be in great measure remedied by the following construction.

The lamp consists of a brass pipe 10 or 12 inches long, and about a quarter of an inch wide, inserted at one end into the reservoir of the oil, and turned up at the other to an elbow, like the bole of a tobacco-pipe, the aperture of which is extended to the width of near two inches. On this aperture is fitted a round plate, having 5, 6, or 7 small holes, at equal distances, round its outer part, into which are inserted as many pipes about an inch long: into these pipes are drawn threads of cotton, all together not exceeding what in the common lamps form one wick: by this division of the wick, the flame exposes a larger surface to the action of the air, the fuliginous matter is consumed and carried off, and the lamp burns clear and vivid.

The reservoir is a cylindric vessel, eight or ten inches wide, composed of three parts, with a cover on the top. The middle partition communicates, by the lateral pipe, with the wicks; and has an upright

Chemical
Furnaces.Chemical
Furnaces.

right open pipe soldered into its bottom, whose top reaches as high as the level of the wick; so that, when this part is charged with oil, till the oil rises up to the wicks in the other end of the lamp, any further addition of oil will run down through the upright pipe into the lower division of the reservoir. The upper division is designed for supplying oil to the middle one; and, for that purpose, is furnished with a cock in the bottom, which is turned more or less, by a key on the outside, that the oil may drop fast enough to supply the consumption, or rather faster, for the overplus is of no inconvenience, being carried off by the upright pipe; so that the oil is always, by this means, kept exactly at the same height in the lamp. For common uses, the middle division alone may be made to suffice; for, on account of its width, the sinking of the oil will not be considerable in several hours burning. In either case, however, it is expedient to renew the wicks every two or three days; oftener or seldomer according as the oil is more or less foul; for its impure matter, gradually left in the wicks, occasions the flame to become more and more dull. For the more convenient renewing of them, there should be two of the perforated plates; that when one is removed, another, with wicks fitted to it, may be ready to supply its place.

One of the black-lead pots, recommended by Dr Lewis for his portable furnace, makes a proper furnace for the lamp. If one is to be fitted up on purpose for this use, it requires no other aperture than

one in the bottom for admitting air, and one in the side for the introduction of the elbow of the lamp. The reservoir stands on any convenient support without the furnace. The stopper of the side aperture consists of two pieces, that it may be conveniently put in after the lamp is introduced; and has a round hole at its bottom fitting the pipe of the lamp. By these means, the furnace being set upon a trevet or open foot, the air enters only underneath, and spreads equally all round, without coming in streams, whence the flame burns steady. It is not advisable to attempt raising the heat higher than about the 450th degree of Fahrenheit's thermometer; a heat somewhat more than sufficient for keeping tin in perfect fusion. Some have proposed giving a much greater degree of heat in lamp-furnaces, by using a number of large wicks; but when the furnace is so heated, the oil emits copious fumes, and its whole quantity takes fire. The balneum, or other vessel including the subject-matters, is supported over the flame by an iron ring, as already described in the sand-bath and still: a bath is here particularly necessary, as the subject would otherwise be very unequally heated, only a small part of the vessel being exposed to the flame. Since the new invention of Argand's lamps, which perfectly consume the oil, attempts have been made to construct lamp-furnaces on their principles; though, on the whole, it is to be doubted whether they are preferable to the above construction or not.

PART. II. P R A C T I C E.

SECT. I. Salts.

§ 1. Of the VITRIOLIC Acid, and its Combinations.

612
Never
found pure.613
Rectifica-
tion.

THE vitriolic acid is never found pure, but always united with some proportion, either of phlogiston or metallic and earthy substances. Indeed there is scarce any kind of earth which does not contain some portion of this acid, and from which it may always some way or other be separable. When pure, the vitriolic acid appears in the form of a transparent colourless liquor. By distilling in a glass retort, the aqueous part arises, and the liquor which is left becomes gradually more and more acid. This operation is generally called the *rectification*, or *dephlegmation*, of the acid. After the distillation has gone on for some time, the water adheres more strongly to what remains in the retort, and cannot be forced over without elevating part of the acid along with it. The remaining acid, being also exceedingly concentrated, begins to lose its fluidity, and puts on the appearance of a clear oil. This is the state in which it is usually sold, and then goes by the name of *oil of vitriol*. If the distillation is still farther continued, with a heat below 600° of Fahrenheit's thermometer, the acid gradually loses more and more of its fluidity, till at last it congeals in the cold, and becomes like ice. In this state it is called the *icy oil of vitriol*. Such exceedingly great concentration, however, is only practised on this acid for curiosity. If the heat be suddenly raised to 600°, the whole of the acid rises, and generally cracks

the receiver. Clear oil of vitriol is immediately turned black by an admixture of the smallest portion of inflammable matter.

The icy-oil of vitriol, and even that commonly sold, attracts the moisture of the air with very great force. Newmann relates, that having exposed an ounce of this acid to the air, from September 1736 to September 1737, at the end of the twelvemonth it weighed seven ounces and two drachms; and thus had attracted from the air above six times its own weight of moisture. This quantity, however, seems extraordinary; and it is probable, that in so long a time some water had been accidentally mixed with it; for Dr Gould, professor at Oxford, who seems to have tried this matter fully, relates, that three drachms of oil of vitriol acquired, in 57 days, an increase only of six drachms and an half. The acid was exposed in a glass of three inches diameter; the increase of weight the first day was upwards of one drachm; in the following days less and less, till, on the fifty-sixth, it scarce amounted to half a grain. The liquor, when saturated with humidity, retained or lost part of its acquired weight according as the atmosphere was in a moist or dry state; and this difference was so sensible as to afford an accurate hygrometer. Hoffman having exposed an ounce and two scruples in an open glass-dish, it gained seven drachms and a scruple in 14 days.

This acid, when mixed with a large quantity of water, makes the temperature something colder than before; but if the acid bears any considerable proportion

614

Attracts
moisture
from the
air.

615

Productive
both of cold
and heat.

Vitriolic Acid and its Combinations.

tion to the water, a great heat is produced, so as to make the vessel insupportable to the hand; and therefore such mixtures ought very cautiously, or rather not at all, to be made in glass vessels, but in the common stone-bottles, or leaden vessels, which are not apt to be corroded by this acid. The greatest heat is produced by equal parts of acid and water.

616
Quantity of alkali saturated by it.

Though the vitriolic acid unites itself very strongly with alkalies, both fixed and volatile, it does not saturate near so much of the latter as of the former. A pound of oil of vitriol will saturate two of the common fixed alkali, but scarce one of volatile alkali. The specific gravity of good oil of vitriol is to water as 17 to 8.

617
Effects on the human body.

If the concentrated acid is applied slightly and superficially to the skin of a living animal, it raises a violent burning heat and pain; but a larger quantity pressed on, so as to prevent the ingress of aerial moisture, occasions little pain or erosion. If diluted with a little water, it proves corrosive in either case. Largely diluted with water, this acid is employed medicinally for checking putrefaction, abating heat, and quenching thirst; in debilities of the stomach, and heart-burn. To persons of weak and unsound lungs, to women who give suck, to hydropic or emaciated persons, it is injurious. Some recommend it as a collyrium for sore eyes; but as it coagulates the animal juices, corroding and indurating the solids, it seems very unfit for being applied to that tender organ.

618
Difficulty of procuring it by itself.

The vitriolic acid is so much used in different arts and manufactures, that the making of it has become a trade by itself; and the procuring it in plenty, and at a cheap rate, would be a very advantageous piece of knowledge to any person who could put it in practice. This, however, is very far from being easily done; for though it exists in almost every mineral substance, the attraction betwixt this acid and the bases with which it unites, is found to be so strong, that we can only decompose such combinations by presenting another substance to the acid, to which it has a greater attraction than that one wherewith it is joined. Thus the first combination is indeed dissolved, but we have another from which it is equally difficult to extricate the acid by itself. Thus, if we want to disengage the vitriolic acid from any metallic substance, suppose iron, this may be easily done by throwing a calcareous earth into a solution of green vitriol. We have now a compound of vitriolic acid with the calcareous earth, which is known by the name of *gypsum* or *selenites*. If we want to decompose this, we must apply a volatile or a fixed alkali; and the result of this will constantly be a new combination, which we are as unable to decompose, and indeed more so, than the first. There are two general methods which have been in use for procuring the vitriolic acid in such quantity as to supply the demands of trade. The one is from pyrites, and the other from sulphur.

I. From *Pyrites*, with the making of *Copperas*, and obtaining the pure Oil of Vitriol from it.

619
Pyrites, where found.

Pyrites are found in large quantity in the coal-mines of England, where most of the *copperas* is made. They are very hard and heavy substances, having a kind of brassy appearance, as if they contained that
N^o 72.

metal; and hence they are called *brasses* by the workmen. A very large quantity of these is collected, and spread out upon a bed of stiff clay to the depth of three feet. After being some time exposed to the air, the uppermost ones lose their metallic appearance, split, and fall to powder. The heaps are then turned, the under part uppermost, so as to expose fresh pyrites to the air. When they are all reduced to powder, which generally requires three years, the liquor, which is formed by the rain-water running from such a large mass, becomes very acid, and has likewise a styptic vitriolic taste. It is now conveyed into large cisterns lined with clay, whence it is pumped into a very large flat vessel made of lead. This vessel, which contains about 15 or 20 tons of liquor, is supported by cast-iron plates about an inch thick, between which and the lead a bed of clay is interposed. The whole rests upon narrow arches of brick, under which the fire is placed. Alongst with the liquor, about half a ton or more of old iron is put into the evaporating vessel. The liquor, which is very far from being saturated with acid, acts upon the iron, and, by repeated filling up as it evaporates, dissolves the whole quantity. By the time this quantity is dissolved, a pellicle is formed on the surface. The fire is then put out; and as such a prodigious quantity of liquor does not admit of filtration, it is left to settle for a whole day, and then is let off by a cock placed a little above the bottom of the evaporating vessel, so as to allow the impurities to remain behind. It is conveyed by wooden spouts to a large leaden cistern, five or six feet deep, sunk in the ground, and which is capable of containing the whole quantity of liquor. Here the *copperas* crystallizes on the sides, and on sticks put into the liquor. The crystallization usually takes up three weeks. The liquor is then pumped back into the evaporating vessel; more iron, and fresh liquor from the pyrites, are added; and a new solution takes place.

Copperas is used, in dyeing, for procuring a black colour; and is an ingredient in making common ink. It is also used in medicine as a corroborant, under the name of *salt of steel*; but before it is used with this intention, it is redissolved in water, and crystallized, with the addition of a little pure oil of vitriol. Whether it is at all mended by this supposed purification, either in appearance or quality, is very doubtful.

This process furnishes us first with a very impure vitriolic acid, which could not be applied to any useful purpose; afterwards with an imperfect neutral salt, called *green vitriol*, which is applicable to several purposes where the pure acid itself could not be used; but still the acid by itself is not to be had without a very troublesome operation.

Though this acid adheres very strongly to iron, it is capable of being expelled from it by fire; yet not without a very violent and long-continued one. If we attempt to distil green vitriol in a retort, it swells and boils in such a manner by the great quantity of water contained in its crystals, that the retort will almost certainly crack; and though it should not, the salt would be changed into an hard stony mass, which the fire could never sufficiently penetrate so as to extricate the acid. It must therefore be calcined previous to the distillation. This is best done in flat iron-pans, set over a moderate fire. The salt undergoes the wa-
tery

Vitriolic Acid and its Combinations.

Vitriolic Acid and its Combinations.

tery fusion, (See FUSION); after which it becomes opaque and white. By a continuance of the fire, it becomes brown, yellow, and at last red. For the purposes of distillation, it may be taken out as soon as it has recovered its solidity.

The dry vitriol, being now reduced to powder, is to be put into an earthen retort, or rather long neck (a kind of retort where the neck issues laterally, that the vapours may have little way to ascend), which it may nearly fill. This retort must be placed in a furnace capable of giving a very strong heat, such as the melting furnace we have already described. A large receiver is to be fitted on; and a small fire made in the furnace, to heat the vessels gradually. White fumes will soon come over into the receiver, which will make the upper part warm. The fire is to be kept of an equal degree of strength, till the fumes begin to disappear, and the receiver grows cool. It is then to be increased by degrees; and the acid will become gradually more and more difficult to be raised, till at last it requires an extreme red, or even white, heat. When nothing more will come over, the fire must be suffered to go out, the receiver be unluted, and its contents poured into a bottle fixed with a glass stopper. A sulphureous and suffocating fume will come from the liquor, which must be carefully avoided. In the retort, a fine red powder will remain, which is used in painting, and is called *colcothar of vitriol*. It is useful on account of its durability; and, when mixed with tar, has been employed as a preservative of wood from rotting; but Dr Lewis prefers finely powdered pit-coal. As a preservative for masts of ships, he recommends a mixture of tar and lamp-black; concerning which he relates the following anecdote.

"I have been favoured by a gentleman on board of a vessel in the East Indies, with an account of a violent thunder-storm, by which the main-mast was greatly damaged, and whose effects on the different parts of the mast were pretty remarkable. All the parts which were greased or covered with turpentine were burst in pieces: those above, between, and below the greased parts, as also the yard-arms, the round-top or scaffolding, coated with tar and lamp-black, remained unhurt."

Oil of vitriol, when distilled in this manner, is always of a black colour, and must therefore be rectified by distillation in a glass retort. When the acid has attained a proper degree of strength, the blackness either flies off, or separates and falls to the bottom, and the liquor becomes clear. The distillation is then to be discontinued, and the clear acid which is left in the retort kept for use.

This was the first method by which the vitriolic acid was obtained; and from its being distilled from vitriol has ever since retained the name of *oil of vitriol*. Green vitriol is the only substance from which it is practicable to draw this acid by distillation; when combined with calcareous earths, or even copper (though to this last it has a weaker attraction than to iron), it resists the fire most obstinately. When distillation from vitriol was practised, large furnaces were erected for that purpose, capable of containing an hundred long necks at once: but as it has been discovered to be more easily procurable from sulphur, this

VOL. IV PART II.

method has been laid aside, and it is now needless to describe these furnaces.

II. To procure the Vitriolic Acid from Sulphur.

This substance contains the vitriolic acid in such plenty, that every pound of sulphur, according to Mr Kirwan's calculation, contains more than one-half of pure acid; which being in a state perfectly dry, is consequently of a strength far beyond that of the most highly rectified oil of vitriol. Common oil of vitriol requires to be distilled to one-fourth of its quantity before it will coagulate when cold; and even in this state it undoubtedly contains some water. No method, however, has as yet been fallen upon to condense all the steams of burning sulphur, at least in the large way, nor is any other profitable way of decomposing sulphur known than that by burning; and in this way the most successful operators have never obtained more than 14 ounces of oil from a pound of sulphur.

The difficulties here are, that sulphur cannot be burnt but in an open vessel; and the stream of air, which is admitted to make it burn, also carries off the acid which is emitted in the form of smoke. To avoid this, a method was contrived of burning sulphur in large glass globes, capable of containing an hog-head or more. The fume of the burning sulphur was then allowed to circulate till it condensed into an acid liquor. A greater difficulty, however, occurs here; for though the sulphur burns very well, its steams will never condense. It has been said, that the condensation is promoted by keeping some warm water continually smoking in the bottom of the globe; and even Dr Lewis has asserted this: but the steam of warm water immediately extinguishes sulphur, as we have often experienced; neither does the fume of burning sulphur seem at all inclinable to join with water, even when forced into contact with it. As it arises from the sulphur, it contains a quantity of phlogiston, which in a great measure keeps it from uniting with water; and the desideratum is not something to make the sulphur burn freely, but to deprive the fumes of the phlogiston they contain, and render them miscible with water. For this purpose nitre has been advantageously used. This consumes a very large quantity of the phlogiston contained in sulphur, and renders the acid easily condensable: but it is plain that few of the fumes, comparatively speaking, are thus deprived of the inflammable principle; for the vessel in which the sulphur and nitre are burnt, remains filled with a volatile and most suffocating fume, which extinguishes flame, and issues in such quantity as to render it highly dangerous to stay near the place. It has been thought that nitre contributes to the burning of the sulphur in close vessels; but this too is a mistake. More sulphur may be burnt in an oil of vitriol globe without nitre than with it, as we have often experienced; for the acid of the sulphur unites with the alkaline basis of the nitre, and forms therewith an unflammable compound, which soon extinguishes the flame, and even prevents a part of the sulphur from being burnt either at that time or any other.

In the condensation of the fumes of sulphur by means of nitre, a remarkable effervescence happens, which naturally leads us to think that the condensation is produced by some struggle between the vitriolic and nitrous fumes.

Vitriolic Acid and its Combinations.

nitrous acids.—Dr Lewis is of opinion, that the acid thus obtained is perfectly free from an admixture of the nitrous acid: but in this he is certainly mistaken; for, on rectifying the acid produced by sulphur and nitre, the first fumes that come over are red, after which they change their colour to white. How the nitrous acid should exist in the liquor, indeed, does not appear; for this acid is totally destructible by deflagration with charcoal: but it does not follow, that because the nitrous acid is destroyed when deflagrated with charcoal, it must likewise be so if dephlagrated with sulphur. Indeed it certainly is not; for the clyffus of nitre made with sulphur is very different from that made with charcoal.

The proportions of nitre to the sulphur, used in the large oil of vitriol works, are not known, every thing being kept as secret as possible by the proprietors. Dr Lewis reckons about six pounds of nitre to an hundred weight of sulphur; but from such experiments as we have made, this appears by far too little. An ounce and an half, or two ounces, may be advantageously used to a pound of sulphur. In greater proportions, nitre seems prejudicial.

627
Lead vessels, an improvement.

A very great improvement in the apparatus for making oil of vitriol, lies in the using lead vessels instead of glass globes. The globes are so apt to be broken by accident, or by the action of the acid upon them, that common prudence would suggest the use of lead to those who intend to prepare any quantity of vitriolic acid, as it is known to have so little effect upon the metal. The leaden vessels, according to the best accounts we have been able to procure, are cubes of about three feet, having on one side a door about six inches wide. The mixture of sulphur and nitre is placed in the hollow of the cube, in an earthen saucer, set on a stand made of the same materials. The quantity which can be consumed at once in such a vessel is about two ounces. To prevent the remains from sticking to the saucer, it is laid on a square bit of brown paper. The sulphur being kindled, the door is to be close shut, and the whole let alone for two hours. In that time the fumes will be condensed. The door is then to be opened; and the operator must immediately retire, to escape the suffocating fumes which issue from the vessel. It will be an hour before he can safely return, and introduce another quantity of materials, which are to be treated precisely in the same manner.

Where oil of vitriol is made in large quantities, the slowness of the operation requires a great number of globes, and constant attendance day and night. Hence the making of this acid is very expensive: The apparatus for a large work usually costs L. 1500.

Vitriolic Acid COMBINED,

628
Vitriolated tartar.

I. *With Fixed Alkali.* Dilute a pound of oil of vitriol with ten times its quantity of water; dissolve also two pounds of fixed alkaline salt in ten pounds of water, and filter the solution. Drop the alkali into the acid as long as any effervescence arises; managing matters so that the acid may prevail. The liquor will now be a solution of the neutral salt called *vitriolated tartar*, which may be procured in a dry form, either by exsiccation or crystallization. In case the latter

method is made use of, some more alkali must be added when it is set to evaporate, for this salt crystallizes best in an alkaline liquor.

Other methods, besides that above described, have been recommended for preparing vitriolated tartar; particularly that of using green vitriol instead of the pure vitriolic acid. In this case the vitriol is decomposed by the fixed alkali: but as the alkali itself dissolves the calx of iron after it is precipitated, it is next to impossible to procure a pure salt by such a process; neither is there occasion to be solicitous about the preparation of this salt by itself, as the materials for it are left in greater quantity than will ever be demanded, after the distillation of spirit of nitre.

Vitriolated tartar is employed in medicine as a purgative; but is not at all superior to other salts which are more easily prepared in a crystalline form. It is very difficultly soluble in water, from which proceeds the difficulty of crystallizing it: for if the acid and alkali are not very much diluted, the salt will be precipitated in powder, during the time of saturation.—It is very difficult of fusion, requiring a strong red heat; but, notwithstanding its fixedness in a violent fire, it arises with the steam of boiling water in such a manner as to be almost totally dissipated along with it by strong boiling.—This salt has been used in making glass; but with little success, as the glass wherein it is an ingredient always proves very brittle and apt to crack of itself.

If, instead of the vegetable fixed alkali, the vitriolic acid is saturated with the fossil one called the *salt of Soda*, a kind of neutral salt will be produced, having very different properties from the vitriolated tartar. This compound is called *Glauber's salt*. It dissolves easily in water, shoots into long and beautiful crystals, which contain a large quantity of water, in consequence of which they undergo the aqueous fusion when exposed to heat. They are also more easily fusible than vitriolated tartar.—This kind of salt was formerly much recommended as a purgative, and from its manifold virtues was intitled by its inventor *sal mirabile*. It is, however, found to possess no virtue different from that of other purgative salts; and its use is, in many places, entirely superseded by a salt prepared from the *bittern*, or liquor which remains after the crystallization of sea-salt, which shall be afterwards described.

II. *With volatile alkali.* Take any quantity of volatile alkaline spirit; that prepared with quicklime is preferable to the other, on account of its raising no effervescence. Drop into this liquor, contained in a bottle, diluted oil of vitriol, shaking the bottle after every addition. The saturation is known to be complete by the volatile smell of the alkali being entirely destroyed. When this happens, some more of the spirit must be added, that the alkali may predominate a little, because the excess will fly off during the evaporation. The liquor, on being filtered and evaporated, will shoot into fine fibrous plates like feathers. This salt, when newly prepared, has a sulphureous smell, and a penetrating pungent taste. It readily dissolves in water, and increases the coldness of the liquor; on standing for a little time, it begins to separate from the water, and

vegetate, or arise in efflorescences up the sides of the glass. It easily melts in the fire; penetrates the common crucibles; and if sublimed in glass vessels, which requires a very considerable heat, it always becomes acid, however exactly the saturation was performed.

This salt has been dignified with the names of *Glauber's secret sal ammoniac*, or *philosophic sal ammoniac*, from the high opinion which some chemists have entertained of its activity upon metals: but from Mr Pott's experiments, it appears, that its effects have been greatly exaggerated. It dissolves or corrodes in some degree all those metals which oil of vitriol dissolves, but has no effect upon those on which that acid does not act by itself.

634
Properties of the salts.

Gold is not touched in the least, either by the salt in fusion, or by a solution of it: the salt added to a solution of gold in aqua-regia occasions no precipitation or change of colour. On melting the salts with inflammable matters, it forms a sulphureous compound, which dissolves gold in fusion, in the same manner as compositions of sulphur and fixed alkaline salt. Melted with silver, it corrodes it into a white calx, which partially dissolves in water: it likewise precipitates silver from its solution in aquafortis. It acts more powerfully on copper; elevates a part of the metal in sublimation, so as to acquire a bluish colour on the surface; and renders the greatest part of the residuum soluble in water. This solution appears colourless, so that it could not be supposed to hold any copper; but readily discovers that it abounds with that metal, by the blue colour it acquires on an addition of volatile alkali, and the green calx which fixed alkalies precipitate. In evaporation it becomes green without addition. Iron is corroded by this salt in fusion, and dissolved by boiling in a solution of it. Zinc dissolves more freely and more plentifully. Lead unites with it, but does not become soluble in water. Tin is corroded, and a part of the calx is soluble in boiling water. Of regulus of antimony also a small portion is made soluble. Alkalies precipitate from the solution a bluish powder. Calcined bismuth-ore treated with its equal weight of the salt, partly dissolved in water into a pale red liquor, which became green from heat, in the same manner as tinctures made from that ore by aqua-regia. The undissolved part yielded still, with frit, a blue glass. On treating manganese in the same manner, aluminous crystals were obtained: the undissolved part of the manganese gave still a violet colour to glass.

635
Gypsum.

III. *With Calcareous Earth.* This combination may be made by saturating diluted oil of vitriol with chalk in fine powder. The mixture ought to be made in a glass; the chalk must be mixed with a pretty large quantity of water, and the acid dropped into it. The glass must be well shaken after every addition, and the mixture ought rather to be over saturated with acid; because the superfluous quantity may afterwards be washed off; the *selenite*, as it is called, or *gypsum*, having very little solubility in water.

This combination of vitriolic acid with chalk or calcareous earth, is found naturally in such plenty, that it is seldom or never made, unless for experiment's sake, or by accident. Mr Pott indeed says, that he found

some slight differences between the natural and artificial gypsum, but that the former had all the essential properties of the latter.

Vitriolic Acid and its Combinations.

The natural gypsums are found in hard, semitransparent masses, commonly called *alabaster*, or *plaster of Paris*. (See ALABASTER, GYPSUM, and PLASTER.) By exposure to a moderate heat, they become opaque, and very friable. If they are now reduced to fine powder, and mixed with water, they may be cast into moulds of any shape: they very soon harden without shrinking; and are the materials whereof the common white images are made. This property belongs likewise to the artificial gypsum, if moderately calcined.

636

Mr Beaumé has observed, that gypsum may be dissolved in some measure by acids; but is afterwards separable by crystallization in the same state in which it was before solution, without retaining any part of the acids. This compound, if long exposed to a pretty strong heat, loses great part of its acid, and is converted into quicklime. In glass vessels it gives over no acid with the most violent fire. It may be fused by suddenly applying a very intense heat. With clay it soon melts, as we have observed when speaking of the materials for making crucibles. A like fusion takes place when pure calcareous earth is mixed with clay; but gypsum bubbles and swells much more in fusion with clay than calcareous earth.

Beaumé's observations.

From natural gypsum we see that vitriolated tartar may be made, in a manner similar to its preparation from green vitriol. If fixed alkaline salt is boiled with any quantity of gypsum, the earth of the latter will be precipitated, and the acid united with the alkali. If a mild volatile alkali is poured on gypsum contained in a glass, and the mixture frequently shaken, the gypsum will in like manner be decomposed, and a *philosophic sal ammoniac* will be formed. With the caustic volatile alkali, or that made with quicklime, no decomposition ensues.

IV. *With Argillaceous Earth.* The produce of this combination is the astringent salt called *alum*, the ancients much used in dyeing and other arts. It has its name from the Latin word *alumen*, called *στυπτήρια* by the Greeks; though by these words the ancients expressed a stasactitic substance containing very little alum, and that entirely enveloped in a vitriolic matter. The alum used at present was first discovered in the oriental parts of the world; though we know not when, or on what occasion. One of the most ancient alum-works of which we have any account was that of *Roccho*, now Edeffa, a city of Syria: and from this city was derived the appellation of *Roch-alum*; an expression so little understood by the generality, that it has been supposed to signify *rock alum*. From this, and some works in the neighbourhood of Constantinople, as well as at Phocæa Nova, now Foya Nova, near Smyrna, the Italians were supplied till the middle of the 15th century, when they began to set up works of a similar kind in their own country. The first Italian alum-work was established about 1459 by Bartholomew Perdix, or Pernix, a Genoese merchant, who had discovered the proper matrix, or ore of alum, in the island of Ischia. Soon after the same material was discovered at Tolfa by John de Castro, who had visited the alum manufactories at Constantinople. Having

ving observed the *ilex aquilifolium* to grow in the neighbourhood of the Turkish manufactories, and finding the same near Tolfa, he concluded that the materials for alum were to be found there also; and was quickly confirmed in his suspicions by the taste of the stones in the neighbourhood. These alum-works prospered exceedingly, and their success was augmented by an edict of Pope Pius II. prohibiting the use of foreign alum.

In the 16th century an alum manufactory was erected at Alamaron, in the neighbourhood of Carthage, where it still continues. Several others were erected in Germany; and in the reign of Queen Elizabeth one was erected in England by Thomas Chaloner. The preparation of this salt was not known in Sweden till the 17th century.

The component principles of this salt were long unknown; but at last Messrs Boulduc and Geoffroy discovered, that it consisted of argillaceous earth superaturated with vitriolic acid. This is confirmed by the experiments of other chemists. It is found to redden the tincture and paper of turnsole; and on taking away the superabundant acid, it loses its solubility and all the other properties of alum. Mr Morveau, indeed, will not admit of a superabundance of acid in alum, which he thinks would necessarily be separated by edulcoration and crystallization; and he is of opinion with Mr Kirwan, that the turning vegetable juices red is not any unequivocal sign of the presence of an acid. In the present case, however, we certainly know that there is a superabundance of acid, and that a certain portion of the vitriolic acid adheres to the clay less tenaciously than the remainder. If we put a piece of iron into a solution of alum, it will attract this portion of acid; and the vitriolated clay, when deprived of the superfluous quantity, will fall down to the bottom in an insoluble powder.

Alum in its ordinary state contains a considerable quantity of water, and crystallizes by proper management into octohedral and perfectly transparent and colourless crystals. When exposed to a moderate fire, it melts, bubbles, and swells up; being gradually changed into a light, spongy, white mass, called *burnt alum*. This, with the addition of some vitriolic acid, may be crystallized as before. The principles it contains, therefore, are water, vitriolic acid, and argillaceous earth. The proportions may be ascertained in the following manner. 1. The water and superfluous vitriolic acid may be dissipated by evaporation, or rather distillation; and the loss of weight sustained by the salt, as well as the quantity of liquid which comes over into the receiver, shows the quantity of aqueous phlegm and unsaturated acid. 2. By combining this with as much caustic fixed alkali as is sufficient to saturate the acid which comes over, we know its proportion to the water; and by redistilling this new compound, we have the water by itself. 3. The earth may be obtained by precipitation with an alkali in its caustic state, either fixed or volatile: but this part of the process is attended with considerable difficulty; for the alkalies first absorb the superfluous acid, after which the earth combined to saturation with the acid falls to the bottom, and the digestion with the alkaline salt must be continued for a very considerable time before the acid is totally separated. By analysing alum in this manner, Mr Bergman determined the principles of

alum to be 38 parts of vitriolic acid, 18 of clay, and 44 of water, to 100 of the crystallized salt.

It has been a question among chemists, whether the earth of alum is to be considered as a pure clay or not. The salt was extracted from common clay by Messrs Hellot and Geoffroy. The experiment was repeated with success by Mr Pott; but he seemed to consider it rather as the production of a new substance during the operation, than a combination of any principle already existing with the vitriolic acid. Margraaf, however, from some very accurate experiments, demonstrated, that all kinds of clay consist of two principles mechanically mixed; one of which constantly is the pure earth of alum. This opinion is espoused by Bergman; who concludes, that since an equal quantity of it may be extracted from clay by all the acids, it can only be mixed with these clays; for if it was generated by the menstrua during the operation, it must be procured in different quantities, if not of different qualities also, according to the difference of the solvents made use of. Notwithstanding this, the matter seems to be rendered somewhat obscure by an experiment of Dr Lewis. "Powdered tobacco-pipe clay (says he) being boiled in a considerable quantity of oil of vitriol, and the boiling continued to dryness, the matter when cold discovers very little taste, or only a slight acidulous one. Exposed to the air for a few days, the greatest part of it was changed into lanuginous efflorescences tasting exactly like alum. The remainder, treated with fresh oil of vitriol, in the same manner exhibits the same phenomena till nearly the whole of the clay is converted into an astringent salt." Hence he concludes, that the clay is in some degree changed before the aluminous salt is produced. Without this supposition, indeed, it is difficult to see why the salt should not be produced immediately by the combination of the two principles. An hundred parts of crystallized alum requires, according to Mr Bergman, in a mean heat 1412 parts of distilled water, but in a boiling heat only 75 of the same parts for its solution. The specific gravity of alum, when computed from the increase of bulk in its solution, is 2.071 when the air-bubbles are abstracted; but if they are suffered to remain, it is no more than 1.757. These bubbles consist of aerial acid, but cannot be removed by the air-pump, though they fly off on the application of heat.

The ores from which alum is prepared for sale, according to Mr Bergman, are of two kinds; one containing the alum already formed, the other its principles united by roasting. What he calls the aluminous schist, is nothing but an argillaceous schist impregnated with a dried petroleum, from whence the oil is easily extracted by distillation; but by applying proper menstrua it discovers several other ingredients, particularly an argillaceous martial substance, frequently amounting to $\frac{1}{4}$ of the whole; a siliceous matter amounting to $\frac{1}{8}$; and commonly also a small proportion of calcareous earth and magnesia; the rest being all pyritous. By roasting this ore the bituminous part is destroyed and the pyrites decomposed; on which part of the vitriolic acid adheres to the iron of the pyrites, and the rest to the pure clay of the schist, forming green vitriol with the former, and alum with the latter. If any calcareous earth or magnesia are present, gypsum and Epsom salt will be produced at the same time. No salt is obtained by

by lixiviating this schist before calcination, though Mr Bergman thinks nothing more is necessary for the production of the salt but the presence of a pyrites. This, he tells us, is generally dispersed through the mass in form of very minute particles, though it sometimes appears in small nuclei. The goodness of the ore, therefore, depends on the proper proportion of the pyrites to the clay, and its equal distribution through the whole. The most dense and ponderous is most esteemed, while that which contains so much pyrites as to be visible is rejected as having too much iron. The ore which produces less than four pounds of alum from 100 of the ore does not pay the expence of manufacturing in Sweden. Sometimes this kind of ore produces salts without the application of fire; but this must be attributed to a kind of spontaneous calcination.

That species of ore which contains the principles already united into alum, according to Mr Bergman, is to be met with only in volcanic countries; and of this kind are the principal Italian ores of alum, particularly that employed at Tolfa near Cincelles, for boiling the Roman alum. Mr Monnet, however, is of opinion, that even this ore does not contain alum perfectly formed, but a combination of nearly equal parts of clay and sulphur, which, by exposure to air during calcination, is converted into alum. He found a little martial earth also contained in it, to which he ascribes the reddish colour of that alum. The aluminous ore at Solfatara in Italy consists of old lava whitened by the phlogisticated vitriolic acid. The clay thus becomes a component part of the aluminous salt, and the mass effloresces in the same manner, and for the same reason, as the mass left after boiling tobacco-pipe clay in oil of vitriol mentioned by Dr Lewis. Mr Bergman, who examined this ore, found, that 100 pounds of it contained eight of pure alum, besides four of pure clay; and that the remainder was siliceous. This proportion, however, must be very variable, according to the quantity of rain which falls upon the ore.

A variety of aluminous ores are to be met with in different parts of the world. In Haffia and Bohemia this salt is obtained from wood impregnated with bitumen. At Helsingborg in Scania, a turf is found consisting of the roots of vegetables mixed with nuts, straw, and leaves, often covered with a thin pyritous cuticle, which, when elixated, yields alum: Even the sulphureous pyrites is generally mixed with an argillaceous matter, which may be separated by menstrua. In some places, sulphur, vitriol, and alum are extracted from the same material. The sulphur rises by distillation; the residuum is exposed to the air till it effloresces, after which a green vitriol is obtained by lixiviation, and alum from the same liquor, after no more vitriol will crystallize. The *alum slate*, from which this salt is made near York in England, contains a considerable quantity of sulphur; and therefore produces alum on the principles already mentioned.

Mr Bergman has given very particular directions for the preparation of this salt from its ores, and minutely describes the several operations which they must undergo. These are,

1. ROASTING. This is absolutely necessary in order to destroy the pyrites; for on this the formation of the alum entirely depends; as the sulphur of the pyrites will not part with its phlogiston without a burning

heat in the open air. By long exposure to the air, indeed, the same effect will follow; but unless the ore be of a particular kind, and loose in texture, so that the air can freely pervade it, the process we speak of cannot take place. The hard ores, therefore, cannot be treated in this manner; and the earthy ores are not only unfit for spontaneous calcination, but for roasting also, as they will not allow the air to pervade them and extinguish the fire. Such as are capable of spontaneous calcination, should be supplied with some quantity of water, and laid on a hard clay bottom, as directed for making green vitriol. The roasting is performed in Sweden in the following manner. Small pieces of the ore are strewed upon a layer of burning sticks to the thickness of half a foot. When the sticks are consumed, these are covered, nearly to the same thickness, with pieces burned before and four times lixiviated: Thus, strata are alternately laid of such a thickness, and at such intervals of time, that the fire may continue, and the whole mass grow hot and smoke, but not break out into flame. The upper strata may sometimes be increased to a double thickness on account of the long continuance of the fire. When eight strata are laid, another row is placed contiguous to the former; when this is finished, a third; and so on until the heap be of a proper size, which rarely requires more than three rows. When the ore is once roasted, it still contains so much phlogiston that water acts but little upon it; but after the operation is two or three times repeated, the ore yields its principles more freely: the roasting may even be repeated to advantage till the whole be reduced to powder. The bitumen keeps up the fire; for which reason alternate layers of the crude ore are used; and in rainy weather these layers of unburnt ore should be thicker. An heap, 20 feet broad at the base, two feet at the top, and consisting of 26 rows, is finished in three weeks, but requires two or three months to be well burned, and three weeks to cool. The greater pyritous nuclei explode like bombs. In this process the sulphur of the pyrites is slowly consumed, and the phlogisticated acid, penetrating the mass, is fixed; after which the remaining phlogiston is gradually dissipated. The chief art consists in moderating the heat in such a manner as to avoid with safety the two extremes; for too small a fire would not be capable of forming the salt, while a heat too strong would destroy it by melting the ore. The scoria are insoluble in water, and therefore thrown away as useless. They are produced by violent winds, or by a strong heat too much closed up; for it is necessary to make holes in the red strata, that the fire may reach the black stratum which is to be laid on. Another method of burning was invented by the celebrated Rinman, and is practised at a place called *Garphyttan* in Sweden. There the ore itself is set on fire; and after burning is boiled, and yields alum in the same manner as the former. The heaps are formed in the following manner: First the schist, burning from the furnace, is laid to the depth of four feet; if the fire be slow, then wood is added; after that a thin stratum of elixated schist; the third consists of schist not burned; and the fourth of elixated schist a foot and a half thick; after that the burning schist, and so on. This method, however, is attended with some inconveniences. The vitriolic acid is partly dissipated by the fire, and thus the

Vitriolic Acid and its Combinations.

669 Method of burning the hard ores at Tolfa in Italy.

the quantity of alum is diminished: so much schist also is requisite in this method that it cannot all be elixated; and thus the heap must be perpetually increasing. The hard ores containing bitumen, such as those of Tolfa, are burned upon wood for some hours like limestone, until they become pervious to water, and effloresce. The fire is extinguished as soon as the flame becomes white, and the smell of sulphureous acid begins to be perceived. When the ore cools, those particles which were nearest to the fire are placed outermost, and those which had been outermost within, the fire being again lighted. The ore is sufficiently burned when it can be broken with the hands. It is then heaped up near certain trenches, and watered five times a-day, particularly when the sun shines clear; the operation being destroyed by a continued rain and cloudy sky. In some places the ore is first burned and afterwards elixated; neither is there any way of knowing the proper methods of managing it but by experiment.

670 Method of elixating the burned ore at Garphyttan with cold water.

2. ELIXATION. This is performed in some places with hot, and at others with cold, water. At Garphyttan in Sweden, where the latter method is chosen, the receptacles, in the year 1772, were of hewn stone, having their joints united by some cement capable of resisting the liquor. Every set consisted of four square receptacles disposed round a fifth, which was deeper than the rest. The first receptacle is filled with roasted schist, and the ore lies in water for 24 hours; the water is then drawn off by a pipe into the fifth; from thence into the second, containing schist not yet wasted; from that, in like manner, after 24 hours, through the fifth into the third, and so into the fourth. The lixivium is then conveyed to the fifth, and allowed to stand in it; and lastly, is drawn off into a vessel appropriated for its reception.—In other places the water passes over the schist that has been washed three times for six hours; then that which has been twice washed, next what has been once washed, and lastly, the ore which has been newly roasted. Those who superintend the alum manufactories are of opinion that the alum is destroyed by passing the water first over the newly burnt ore, and then over that which has been previously elixated.

671 Other methods.

672 Singular circumstance by which the alum may be destroyed.

673 Of the proper strength of the lixivium before boiling.

The lixivium, before boiling, ought to be as richly impregnated with alum as possible, in order to save fuel, though this is frequently neglected. In some places the taste is used as the only criterion; but in others the weight of water which fills a small glass bottle is divided into 64 equal parts, each of which is called in Sweden a *panning*; and the quantity by which the same bottle, full of lixivium, exceeds it when filled with water, is supposed to indicate the quantity of salt dissolved.—This method may undoubtedly be reckoned sufficiently accurate for work conducted on a large scale: and though Mr Bergman gives formulæ by which the matter may be determined to a scrupulous exactness, it does not appear that such accuracy is either necessary or indeed practicable in works conducted in a great way.

Those who manage the alum manufactories assert, that the cold lixivium ought to be made no richer than when the weight of the bottle filled with lixivium exceeds it when filled with water by $4\frac{1}{2}$ pannings,

which shows the water to be loaded with $\frac{1}{7.7}$ of its weight of alum. If the overplus amounts to six pannings, which indicates its containing $\frac{1}{8}$ of salt, crystals are then deposited.—Congelation is of no use to concentrate the aluminous lixivium; for water saturated with alum freezes almost as readily as pure water.

3. BOILING THE LEY FOR CRYSTALLIZATION. The ley being first brought from the pits through canals made for the purpose, is put into a leaden boiler, at the back of which is a reservoir, out of which the loss sustained by evaporation is constantly supplied, so that the surface of that in the boiler continues always nearly at the same height. Various signs are used by different manufacturers to know when the ley is properly evaporated: some determining the matter by the floating of a new laid egg; others by dropping a small quantity on a plate, and observing whether it crystallizes on cooling; and lastly, others weigh the lixivium in the bottle above-mentioned. The boiling is supposed to be finished if the increase of weight be equal to 20 pannings; that is, if the water be loaded with $\frac{1}{8.8}$ of its own weight. It might, however, take up above $\frac{1}{7}$ of its weight, or nearly 27 pannings; but as it has to be depurated by standing quiet before the crystals are formed, the liquor must not be fully saturated with salt.

The lixivium, when sufficiently concentrated by evaporation, flows through proper channels into coolers, where it is allowed to rest for about an hour to free it from the grosser sediment; after which it is put into wooden or stone receptacles to crystallize. In eight or ten days the remaining liquor, commonly called *mother ley*, or *magistral water*, is let off into another vessel. A great number of crystals, generally small and impure, adhere to the bottom and sides of the vessel, which are afterwards collected and washed in cold water.

When a sufficient quantity of the small crystals are collected, they must then be put into the boiler for depuration. They are now dissolved in as small a quantity of water as possible; after which the lixivium is poured into a great tub containing as much as the boiler itself. In 16 or 18 days the hoops of the tub are loosed, and the aluminous mass bound with an iron ring; and in 28 days more the residuum of the solution is let out through a hole, and collected in a trench; after which the saline mass, which at Garphyttan in Sweden amounts to 26 tons, is dried and sold as depurated alum. The boiler emptied for the first crystallization is next filled two-thirds full with the magistral lixivium; and as soon as the liquor arrives at the boiling point, the other third is filled with crude lixivium, with which the evaporation is also constantly supplied. A certain quantity of the aluminous impurities left by washing the salts of the first crystallization in water is then added, and the above described process repeated. Only the first boiling in the spring is performed with the crude lixivium alone, the rest are all done as just now related.—Mr Bergman remarks, that the time required for crystallization may undoubtedly be shortened. The reservoirs used in Sweden for this purpose (he says), are deep, and narrow at the top; on which account they are not only long

 long in cooling, but the evaporation, which is absolutely necessary for the crystallization, goes on very slowly, excepting in extremely warm weather, at the same time that the doors and windows are disposed in such a manner as to direct a current of air along the surface. In Italy he tells us that conical reservoirs are used with the wide part uppermost.

679
 Alum cannot be formed by merely evaporating and cooling the ley, on account of the excess of acid. It is remarkable, that pure alum cannot be obtained in very considerable quantity by merely evaporating and cooling the ley. The reason of this is, that the lixivium sometimes acquires such a consistence, that it both crystallizes with difficulty, and produces impure crystals. The cause was unknown till the time of Mr Bergman, who has shown that it proceeds from an excess of vitriolic acid. Hence also we may see the reason why alkaline salts, volatile alkali in its pure state, or even putrefied urine, when added to this thick solution, produce good crystals of alum when they cannot be obtained otherwise. It is remarkable that this impediment to crystallization is not removed by mineral alkali, though it is so by the vegetable and volatile alkalies, which is a phenomenon hitherto unexplained. According to our author, however, an addition of pure clay, to absorb the superabundant acid, is preferable to any other; and indeed it is reasonable to think so, as the union of vitriolic acid and pure clay forms the salt desired, which is not the case with any of the alkalies.—To ascertain this, he made the following experiments.

680
 This excess cannot be removed by mineral alkali, though it may be by vegetable and volatile alkalies, and best of all by pure clay. 1. He dissolved 215 grains of pure alum in distilled water, in a small cucurbit, and evaporated it over the fire till the surface of the liquor stood at two marks, which indicated, in a former evaporation, that it was fit for crystallization. 2. Having poured out this into a proper glass vessel, he dissolved other 215 grains, and added to the solution $24\frac{1}{2}$ grains of concentrated vitriolic acid. 3. This solution being likewise poured out, the experiment was repeated a third time, with the addition of 53 grains of vitriolic acid; and the glasses being at last set in a proper place for crystallization, the first yielded $155\frac{1}{4}$, the second 130, and the third $100\frac{1}{4}$ grains of alum.

681
 Experiment showing that an excess of vitriolic acid impedes the crystallization of alum. This shows that an excess of vitriolic acid impedes the crystallization of the alum; but to determine how far this could be remedied by the addition of clay, farther experiments were necessary. Having therefore employed a magistral residuum, in which the excess of acid was nearly in the proportion already related, he added two drachms of clay in fine powder to a kanne, or Swedish cantharus, of the liquor: he boiled the mixture for ten minutes; and on separating the clay that remained, he found that $25\frac{1}{2}$ grains were dissolved, which indicates an increase of 141 grains of alum. On gently boiling the liquor for half an hour, 75 grains of the clay were dissolved, which indicated an increase of 416 grains of alum.

682
 Experiment to determine the usefulness of adding clay to the ley. The addition of clay must therefore be much preferable to that of alkaline salts, not only as the former produces a considerable increase of alum, but also as there is no danger of adding too much; for we have already shown, that when the liquor is entirely deprived of its superabundant acid, the neutralized clay is insoluble in water. The earth itself, however, dissolves so slowly, that there is not the least danger of

683
 Advantages of using clay rather than alkalies. the acid being oversaturated by simply boiling them together.

the acid being oversaturated by simply boiling them together.

Alum, as commonly made, though depurated by a second crystallization, yet is almost always found contaminated by dephlogisticated vitriol; whence it grows yellow, and deposits an ochre in solution when old. This is equally useful in some arts with the purest kind, and is even so in dyeing where dark colours are required; but where the more lively colours are wanted, every thing vitriolic must be avoided. This is done by the addition of pure clay, which precipitates the iron, and produces an alum entirely void of any noxious or heterogeneous matter. Nor is this contrary to the laws of chemical attraction; for though iron is dissolved by a solution of alum, and the earthy base of alum precipitated, and though in a solution of vitriol and alum the white earth falls first on an addition of alkali, and then the ochre; this happens only in consequence of employing phlogisticated or metallic iron, or such as is but very little dephlogisticated; for if the inflammable principle be any further diminished, the attraction is thereby so much weakened, that the clay has a greater attraction for the vitriolic acid than the iron. The truth of this may be proved in many different ways. Thus, let a portion of alum be dissolved in a solution of highly dephlogisticated vitriol, and an alkali then added, the ochre of the vitriol will be first deposited, and then the clay: and provided there be a sufficient quantity of the latter, the iron will all be precipitated; and hence we see that an aluminous solution mixed only with one of dephlogisticated vitriol may readily be freed from it.

But a solution of alum containing perfect vitriol cannot be freed from it effectually either by clay or alkali; for the former effects no decomposition, and the latter, although it can destroy the vitriol, will undoubtedly decompose the alum in the first place. As long, therefore, as the solution is rich in alum, it may be employed in the common manner; but when the vitriolic salt begins to predominate, it must either be crystallized in its proper form, or be destroyed in such a manner as to produce alum, which may be accomplished in the following manner. Let the lixivium be reduced to a tenacious mass with clay, and formed into cakes, which must be exposed in an open house to the open air. Thus the phlogiston, which is powerfully attracted by the dephlogisticated part of the atmosphere, by degrees separates from the iron, while the clay is taken up by its superior attraction for the acid. The calcination is accelerated by fire; but it must be cautiously employed, lest the acid should be expelled.

In the alum manufactories in Sweden, a considerable quantity of vitriolated magnesia, or Epsom salt, is mixed with the alum. Mr Bergman directs this to be separated by means of an uncalcined calcareous earth, which entirely destroys both the alum and vitriol; falling down to the bottom with the acid in form of a selenitic matter. This must be added to the boiling liquor gradually, lest the effervescence should cause the mass to swell and run over the top of the vessel. A just proportion destroys both the aluminous and vitriolic salt, on being properly agitated and heated; neither is there any danger of the Epsom salt.

Vitriolic Acid and its Combinations.

Vitriolic Acid and its Combinations.

689 Superfluous acid might be advantageously distilled.

salt being decomposed in this process, the uncalcined earth being unable to separate the magnesia from the acid. Were this method followed in the Swedish manufactories, he is of opinion, that as much Epsom salt might be produced from them as would supply the consumpt of that kingdom.

With regard to the quantity of superfluous acid found in the magistral lixivium, Mr Bergman informs us, that it amounted to five ounces in one kanne; so that in a single boiler there is nearly 250 lb. But vitriol, when well dephlogisticated, retains its acid so loosely that it may be easily separated by fire. He has no doubt, therefore, that if the surface of such a lixivium were first increased in order to let the phlogiston evaporate, the liquor might afterwards be advantageously committed to distillation for the sake of its acid.

From what has been above delivered, the necessity will be sufficiently apparent of not continuing the coction even with pure clay to perfect saturation of the liquor: and this is further confirmed by M. Beaumé, who relates, that having boiled four ounces of earth of alum with two ounces of the salt, in a sufficient quantity of water, the acid became saturated to such a degree with earth, that the liquor lost its aluminous taste entirely, and assumed that of hard spring water. After filtration and evaporation, only a few micaceous crystals, very difficult of solution, were formed by letting the liquor stand for some months.--- Dr Sieffert informs us, that by boiling half an ounce of alum with half a drachm of slaked lime, cubical crystals of alum may be obtained.

690 Epsom salt.

V. *With Magnesia*. The earthy substance called *magnesia alba* is never found by itself, and consequently this combination cannot originally take place by art. The vitriolic acid, however, is found combined with magnesia in great plenty in the bitter liquor which remains after the crystallization of common salt; from whence the magnesia is procured by precipitating with a fixed alkali. If this liquor, which, when the common salt is extracted, appears like clean oil of vitriol, is set by for some time in a leaden vessel, a large quantity of salt shoots, very much resembling Glauber's sal mirabile. This salt is in many places sold instead of the true Glauber's salt; and is preferred to it, because the true sal mirabile calcines in dry air, which the spurious kind does not. If after the first crystallization of the bittern, the remainder is gently evaporated farther, a fresh quantity of Glauber's salt will shoot; and if the liquor is then hastily evaporated, a salt will still be crystallized; but instead of large regular crystals, it will concrete into very small ones, having something of the appearance of snow when taken out of the liquid. These salts are essentially the same, and are all used in medicine as purgatives. The salt shot into small crystals is termed *Epsom salt*, from its being first produced from the purging waters at Epsom in England. The bittern affording this kind of salt in such great plenty, these waters were soon neglected, as they yielded it but very sparingly, and the quantity prepared from them was insufficient for the demand. Neumann says, that having inspissated 100 quarts of Epsom water, he scarce obtained half an ounce of sa-

Nº 72.

line matter.—According to Mr Scheele's experiments, if a solution of Epsom and common salt be mixed together, a double decomposition ensues, and the mixture contains Glauber's salt and a combination of magnesia with marine acid. From this lixivium the Glauber's salt may be crystallized in winter, but not in summer; a great degree of cold being necessary for this purpose. From twelve pounds of Epsom salt and six of common salt, Mr Scheele obtained, in a temperature three degrees below the freezing point, six pounds of Glauber salt; but in a degree of cold considerably greater, the produce was seven pounds and three quarters.

VI. *With Silver*. Oil of vitriol boiled on half its weight of silver-filings, corrodes them into a saline mass. This substance is not used in medicine nor in the arts. The only remarkable property of it is, that it has a very strong attraction for mercury; coagulating and hardening as much quicksilver as the acid weighed at first. If the hard concrete be diluted with fresh acid, it melts easily in the fire, and does not part with the mercury in the greatest heat that glass vessels can sustain. The vitriolic acid, by itself, strongly retains mercury, but not near so much as when combined with silver.

Silver thus corroded by the vitriolic acid, or precipitated by it from the nitrous, may in great part be dissolved, by cautiously applying a very little water at a time; and more effectually by boiling in fresh oil of vitriol.

VII. *With Copper*. With this metal the vitriolic acid cannot be combined, unless in its concentrated state, and strongly heated. If pure oil of vitriol is boiled on copper filings, or small pieces of the metal, it dissolves it into a liquor of a deep blue colour, which easily crystallizes. The crystals are of a beautiful blue colour, and are sold under the name of *blue vitriol* or *Roman vitriol*.

Where sulphur is found in great plenty, however, Roman vitriol is made by stratifying thin plates of copper with sulphur; and upon slowly burning the sulphur, its acid corrodes the copper. The metal is then to be boiled in water, that the saline part may be dissolved. The operation is to be repeated till all the copper is consumed; and all the saline liquors are to be evaporated together to the crystallizing point. By this method, however, a great part of the acid is lost; and in Britain, where the sulphur must be imported, we should think the pure acid preferable for those who prepare blue vitriol.

This salt, on being exposed to the fire, first turns white, then of a yellowish red colour. On urging it with a strong fire, the acid slowly exhales, and a dark red calx of copper remains. The whole of the vitriolic acid cannot be expelled from copper by heat: as much of it still remains as to render a part of the metal soluble in water. After this soluble part has been extracted, a little acid is still retained, amounting to about $\frac{1}{4}$ of the calx.

Vitriol of copper is employed in medicine as a caustic, in which respect it is very useful; but when used internally, is dangerous, as indeed all the preparations of copper are found to be. It has, nevertheless, according

tions.

cording to Neumann, been recommended in all kinds of intermittents, and the lepra. The smallest portion, he says, occasions a sickness and nausea; a somewhat larger, reaching and violent vomitings, accompanied often with convulsions. If the quantity taken has been considerable, and is not soon discharged by vomiting, the stomach and intestines are corroded, intense pains, inflammations, and death, succeed.

696
Iron.

VIII. *With Iron.* The vitriolic acid does not act upon this metal till considerably diluted. Common oil of vitriol requires to be mixed with ten or twelve times its quantity of water before it will act briskly on the metal. In this state it effervesces violently with iron filings, or small bits of the metal, and a great quantity of inflammable vapour is discharged (see AIR). The liquor assumes a fine green colour; and by evaporation and slow cooling, very beautiful rhomboidal crystals are formed. These are named *salt of steel*, and are used in medicine; but for the salt made with the pure acid and iron, the common copperas, made with the impure acid extracted from pyrites, is commonly substituted. This is generally esteemed a venial fraud, and no doubt is so in medicinal respects; but when it is considered, that, by this substitution, common copperas is imposed on the ignorant, at the price of 2 s. per pound, the affair appears in a different light.

697
Salt of steel.

698
Precipitation of iron
from the
vitriolic
acid.

Pure vitriol of iron is originally of a much more beautiful appearance than common copperas, and retains its colour much better; the reason of which is, that the salt thus prepared has more phlogiston than the copperas. If either of the kinds, however, are exposed to the air for a sufficient length of time, part of the acid is dissipated, and the vitriol becomes yellowish or brownish. If the salt is now dissolved in water, a brown precipitate falls, which is part of the iron in a calcined state. If the liquor is separated from this precipitate by filtration, a similar one forms in a short time, and by long standing a considerable quantity subsides. According to Dr Lewis, the precipitation is greatly expedited by a boiling heat; by which more of the metal separates in a few minutes than by standing without heat for a twelvemonth. This change takes place in no other metallic solutions.

699
Yellow for
house paint-
ing.

700
Preserva-
tive for
wood.

The calx of iron, precipitated by quicklime from green vitriol, appears, when dry, of a yellow colour; and is recommended in the Swedish transactions, instead of yellow ochre, as a colour for house-painting. Solutions of green vitriol are also recommended for preserving wood, particularly the wheels of carriages, from decay. When all the pieces are fit for being joined together, they are directed to be boiled in a solution of vitriol for three or four hours; and then kept in a warm place for some days to dry. By this preparation, it is said, wood becomes so hard, that moisture cannot penetrate it; and that iron nails are not so apt to rust in this vitriolated wood as might be expected, but last as long as the wood itself.

701
Tin.

IX. *With Tin.* This metal cannot be dissolved in the vitriolic acid, but in the same manner as silver; namely, by boiling concentrated oil of vitriol to dryness upon filings of the metal. The saline mass may then be dissolved in water, and the solution will crystallize. The salt, however, formed by this union, is not applied to any useful purpose. A salt of tin, indeed,

VOL. IV. Part II.

formed by the union of vitriolic acid with this metal, has been recommended for some medical purposes, and processes are given for it in the dispensatories; but they have never come much into practice.

X. *With Lead.* While lead is in its metallic state, the vitriolic acid acts very little upon it, either in a diluted or concentrated state; but if the metal is dissolved in any other acid, and oil of vitriol added, a precipitation immediately ensues, which is occasioned by the combination of vitriolic acid with the lead. This precipitate will be more or less white as the metal is more or less deprived of its phlogiston by calcination before solution. If a little strong spirit of nitre is poured upon *litharge*, which is lead calcined to the greatest degree possible without vitrification, the acid unites itself to the metal with considerable effervescence and heat. Some water being now poured on, and the phial containing the mixture shaken, a turbid solution of the litharge is made. If a little oil of vitriol is then added, it throws down a beautifully white precipitate; and the acid of nitre, being left at liberty to act upon the remaining part of the litharge, begins anew to dissolve it with effervescence. When it is again saturated, more oil of vitriol is to be dropped in, and a white precipitate is again thrown down. If any of the litharge is still undissolved, the nitrous acid, being set at liberty a second time, attacks it as at first; and by continuing to add oil of vitriol, the whole of the litharge may be converted into a most beautiful and durable white. Unfortunately this colour cannot be used in oil, though in water it seems superior to any. If the process is well managed, an ounce of spirit of nitre may be made to convert several pounds of litharge into a white of this kind.

Vitriolic
Acid and its
Combina-
tions.

702
Lead.

703
A beautiful
white co-
lour.

XI. *With Quicksilver.* The dissolution of quicksilver in vitriolic acid cannot be performed but by a concentrated oil and strong boiling heat. The metal is first corroded into a white calx, which may afterwards be easily dissolved by an addition of fresh acid. Every time it is dissolved, the mercury becomes more and more fixed and more difficult to dry. If the exsiccation and dissolution has been repeated several times, the matter becomes at last so fixed as to bear a degree of red heat. This combination is the basis of a medicine formerly of some repute, under the name of *turbith mineral*. The process for making turbith mineral is given by the author of the Chemical Dictionary as follows:

704
Quicksil-
ver.

“Some mercury is poured into a glass retort, and upon it an equal quantity of concentrated oil of vitriol, or more, according to the strength of the acid. These matters are to be distilled together, in the heat of a sand-bath, till nothing remains in the retort but a dry saline mass, which is a combination of the vitriolic acid and mercury. The acid which passes into the receiver is very suffocating and sulphureous; which qualities it receives from the phlogiston of the mercury. The white saline mass which is left at the bottom of the retort is to be put into a large vessel; and upon it are to be poured large quantities of hot water at several different times. This water weakens the acid, and takes it from the mercury; which is then precipitated towards the bottom of the vessel, in form of a very shining yellow powder. The water with

705
Turbith
mineral.

Vitriolic
Acid and its
Combina-
tions.

which it is washed contains the acid that was united with the mercury, and likewise a little mercury rendered soluble by means of the very large quantity of acid.

Most chemists have believed, that a portion of vitriolic acid remains united with the turbith mineral, only too little to render it soluble in water. But Mr Beaumé, having examined this matter, affirms, that turbith mineral contains no acid, when it has been sufficiently washed; and that, by frequently boiling this preparation in a large quantity of distilled water, not a vestige of acid will adhere to it."

706
Dr Lewis's
directions

Dr Lewis, who is of opinion that the whole of this mercurial calx is soluble in a very large quantity of water, desires the water with which it is washed to be impregnated with some alkaline salt; which makes the yield of turbith greater than when pure water is used. The author of the Chemical Dictionary also observes, that the precipitate remains white till well freed from the acid; and the more perfectly it is washed, the deeper yellow colour it acquires.

707
Zinc.

XII. *With Zinc.* This semimetal is not acted upon by the vitriolic acid in its concentrated state; but, when diluted, is dissolved by it with effervescence, and with the extrication of an inflammable vapour in the same manner as iron. Neumann observes, that, during the dissolution, a grey and blackish spongy matter fell to the bottom; but, on standing for some days, was taken up, and dissolved in the liquor, nothing being left but a little yellowish dust scarcely worth mentioning. Six parts of oil of vitriol, diluted with an equal quantity of water, dissolves one part of zinc.

708
White vi-
triol.

The product of this combination is *white vitriol*; which is used in medicine as an ophthalmic, and in painting for making oil-colours dry quickly: what is used for this purpose, however, is not made in Britain, but comes from Germany. It is made at Goslar by the following process. An ore containing lead and silver, having been previously roasted for the obtaining of sulphur (see METALLURGY), is lixiviated with water, and afterwards evaporated in leaden boilers, as for the preparation of green vitriol: but here a regular crystallization is prevented; for when the salt has assumed any kind of crystalline form, these crystals are made to undergo the watery fusion in copper caldrons. It is then kept constantly stirring till a considerable part of the moisture is evaporated, and the matter has acquired the consistence of fine sugar. White vitriol generally contains some ferruginous matter, from which it may be entirely freed by some fresh zinc; for this semimetal precipitates from the vitriolic acid all other metallic substances; but notwithstanding this strong attraction, the vitriolic acid is more easily expelled by distillation from white than green or blue vitriol. Towards the end of the distillation of white vitriol, the acid arises exceedingly concentrated, though sulphureous: so that, if mixed with common oil of vitriol, it will heat it almost as much as oil of vitriol heats water.

709
Regulus of
antimony.

XIII. *With Regulus of Antimony.* To combine vitriolic acid with regulus of antimony, the same method must be used, as directed for uniting it with quicksilver, for making turbith mineral, viz. to employ a very concentrated acid, and to distil in close vessels. The same

phenomena also occur in this case as in making turbith mineral; a very suffocating sulphureous acid rises; and, as Mr Geoffroy observes, a true sulphur sublimes into the neck of the retort; a white, saline, tumefied, mass remains in the vessel; and when the vessels are unluted, a white fume issues, as in the smoking spirit of libavins. See *Combinations of marine acid with tin*, infra.

XIV. *With Regulus of Cobalt.* From a combination of the vitriolic acid with cobalt, a red salt may be obtained. To procure it, one part of cobalt, reduced to a very fine powder, may be mixed with two or three of concentrated acid, diluting the liquor after it has been digested for 24 hours, and then filtering and evaporating it.

XV. *With Arsenic.* Neumann relates, that powdered white arsenic being distilled in a retort with oil of vitriol, a transparent sublimate like glass arose, which in a few days lost its transparency, and became opaque like the arsenic itself. The arsenic remaining in the retort sustained an open fire without any sensible alteration. The author of the Chemical Dictionary says, that if a concentrated vitriolic acid is distilled from arsenic, the acid which comes over smells exactly like marine acid. When the solution is distilled till no more acid rises, the retort is then almost red-hot, and no arsenic is sublimed; but it remains fused at the bottom of the retort; and, when cold, is found to be an heavy, compact mass, brittle and transparent as crystal-glass. This kind of arsenical glass, exposed to the air, soon loses its transparency from the moisture it attracts, which dissolves and partly deliquesces it. This deliquium is extremely acid.—By digesting one part of arsenic with two of concentrated oil of vitriol, diluting the solution with water, and then filtering and evaporating, we obtain a yellowish salt which shoots into pyramidal, transparent, and shining crystals. None of the three last mentioned combinations have been found applicable to any useful purpose.

XVI. *With Oil.* The product of this combination is a thick black substance, very much resembling balsam of sulphur in colour and consistence; to which it is sometimes substituted. If this substance is distilled with a gentle heat, great part of the acid becomes volatile, and evaporates in white fumes, having a pungent smell resembling that of burning sulphur. This goes by the name of *volatile or sulphureous vitriolic acid*; and a salt was formerly prepared from it by saturation with fixed alkali, which was thought to possess great virtues. From its inventor it was called the *sulphureous salt of Stahl*. The most singular property of this volatile acid is, that though the vitriolic in its fixed state is capable of expelling any other acid from its basis, the volatile one is expelled by every acid, even that of vinegar. It is very difficultly condensable, as we have already taken notice; and, when mixed with water, seems scarcely at all acid, but rather to have a bitterish taste.

Several methods have been proposed for procuring this acid from burning sulphur, which yields it in its greatest degree of volatility, as well as concentration; but the produce is so exceedingly small, that none of them are worth mentioning. Dr Priestley has given very good directions for obtaining the volatile vitriolic acid in the form of air. His method was, to pour, on some

Combina-
tions.

some oil of vitriol contained in a phial, a very small quantity of oil olive; as much as was sufficient to cover it. He then applied the proper apparatus for the reception of air in quicksilver (see AIR); and, holding a candle to the phial, the volatile vitriolic acid rushed out in great quantity. Had he received this air in water, instead of quicksilver, the consequence would have been, that some part of it, at least, would have been absorbed by the water, and a sulphureous acid liquor produced. This seems indeed almost the only method of procuring the sulphureous vitriolic acid of any tolerable strength; but it is never required in the form of a liquor, except for experimental purposes. The only useful property hitherto discovered about this kind of acid is, that it is remarkably destructive of colours of all kinds; and hence the fumes of sulphur are employed to whiten wool, &c.

715
Charcoal.

XVII. *With Phlogiston of charcoal.* If charcoal is mixed with concentrated vitriolic acid, and the mixture distilled, the same kind of acid is at first obtained, which comes over when oil is used; and towards the end, when the matter begins to grow dry, a true sulphur sublimes. The best way, however, of producing sulphur from the vitriolic acid is by combining it, when in a perfectly dry state, with the phlogiston. By this means sulphur may very readily be made at any time. The process is generally directed to be performed in the following manner.

716
Sulphur
prepared
from vitri-
olated tartar.

Reduce to fine powder any quantity of vitriolated tartar. Mingle it carefully with a 16th part of its weight of charcoal-dust. Put the whole into a covered crucible set in a melting furnace. Give a heat sufficient to melt the salt; and when thoroughly melted, pour it out on a flat stone. The vitriolated tartar and charcoal will now be converted into a sulphureous mass similar to a combination of alkaline salts with sulphur. See *Alkaline Salts*, below.

717
Spirit of
wine.

XVIII. *With Spirit of wine.* The result of this combination is one of the most extraordinary phenomena in chemistry; being that fluid, which, for its extreme degree of volatility, was first distinguished by the name of *ether*: and now, since a liquor of the like kind is discovered to be preparable from spirit of wine by means of other acids, this species is distinguished by the name of *vitriolic ether*. The method of preparing this subtle liquor recommended by M. Beaumé, seems to be the best of any hitherto discovered.

718
Ether.

Mix together equal parts by weight, of highly rectified spirit of wine and concentrated oil of vitriol, or somewhat more than two measures of spirit of wine with one of the acid. The mixture is to be made in a flint glass retort, the bottom and sides of which are very thin, that it may not break from the heat which is suddenly generated by the union of these two substances. The spirit of wine is first put into the retort, and then the acid is poured in by a glass-funnel, so that the stream may be directed against the side of the glass; in which case it will not exert much of its force on the spirit, but will lie quietly below at the bottom. The retort is now to be very gently shaken, that the acid may mingle with it by little and little. When the mixture is completed, very little more heat will be necessary to make the liquor boil.

This mixture is to be distilled with as brisk and quick a heat as possible; for which reason, immediately

after the acid and spirit are mixed, the retort should be put into a sand furnace heated as much as the mixture is. The distillation should be continued only till about one third of the liquor is come over; if it is continued farther, part of the vitriolic acid rises in a sulphureous state. In the retort a thick, black, acid matter remains, which is similar to a combination of oil of vitriol with any inflammable matter, and from which a little sulphur may be obtained. Along with the sulphureous acid, a greenish oil, called *oleum vitrioli dulcis*, arises, which has a smell compounded of that of the ether and sulphureous acid: and Mr Beaumé has shown that it is compounded of these two; for if it is rectified with an alkali, to attract the acid, it is changed into ether. If, after the distillation of the ether, some water be poured into the retort, the liquor by distillation may be brought back to the state of a pure vitriolic acid.

As the steams of the ethereal liquor are exceedingly volatile, and at the same time a quick fire is necessary to the success of the operation, the receiver must be carefully kept cool with very cold water or with snow. Care must also be taken to prevent any of the sulphureous acid steams from coming over; but as it is impossible to prevent this totally, the liquor requires rectification. This is the more necessary, as a part of the spirit of wine always rises unchanged. From this acid the liquor is easily set free, by adding a small quantity of alkaline salt, and re-distilling with a very gentle heat; but as spirit of wine is likewise very volatile, the distillation must be performed in a very tall glass. Dr Black recommends a matrafs, or bolt-head, with a tin-pipe adapted to the head, so as to convey the steams at a right angle, to be condensed in the receiver. When this fluid is to be prepared in great quantities, the ether, by proper management, may be made to equal half the weight of the spirit of wine employed. Mr Dollfus has made many important experiments on this subject; of which the following is an abstract: 1. Two pounds of vitriolic acid were mixed with as much of spirit of wine, and the mixture distilled with a very gentle fire. The first ten ounces that came over consisted of a liquor strongly impregnated with ether, and of an agreeable odour. This was put by itself and marked A. It was followed by a stronger ethereal liquor, of which a small quantity only would mix with water. Of this there were 12 ounces, which were also put by themselves, and marked B. By continuing the process two ounces more were obtained, which smelled of sulphur, and were marked C. The distillation was now continued with a view to concentrate the vitriolic acid, when three drachms of a thicker kind of ether were found swimming on a weak sulphureous acid. This thick liquid was not in the least volatile, and in consistence resembled an expressed oil. 2. Twenty-four ounces of spirit of wine were now added to the residuum of the former distillation, and the process recommenced. The first seven ounces that came over were poured to the dulcified spirit marked A. Next passed over ten ounces of a tolerably pure ether, which was mixed with the contents of B; besides two ounces that had a sulphureous smell, which were mixed with C. By a repeated dephlegmation of what remained in the retort were obtained five ounces of a weak sulphureous acid; and

Vitriolic
Acid and its
Combina-
tions.

Vitriolic
Acid and its
Combina-
tions.

the remainder being again mixed with 20 ounces of spirit of wine, yielded first six ounces of the liquor marked A; then four ounces of pure ether put into that marked B; and after that another ounce marked C. By continuing the distillation four ounces of weak sulphureous acid were obtained, on which floated a little oil of wine. 3. The remainder, which was very thick, and covered with a slight pellicle, was mixed with 20 ounces of spirit of wine, and yielded five ounces of dulcified spirit marked A; eight ounces of pure ether marked B; and at last one ounce of the same, which had rather a sulphureous smell. This was followed by a few drops of acid; but the remainder frothed up with such violence, that an end was put to the operation, in order to prevent its passing over into the receiver.

By these four distillations there were obtained from six pounds of spirit of wine and two of oil of vitriol, 28 ounces of dulcified spirit of vitriol and 38 of ether; which last, when rectified by distillation over manganese, yielded 28 ounces of the best ether. At the end of this distillation were produced 13 ounces of weak acetous acid; and the liquor of the last running marked C, afforded, by rectification, four ounces of good ether. The sulphureous acid liquor yielded four ounces of weak acetous acid, and three drachms of naphtha resembling a distilled oil in consistence.

By these processes the vitriolic acid was rendered quite thick and black; its weight being reduced to 24 ounces. The blackness was found to be owing to a powder which floated in the liquid, and could neither be separated by subsiding to the bottom nor rising to the top. The liquor was therefore diluted with eight ounces of water, and filtered through powdered glass; by which means the black substance was collected, partly in powder, and partly in grains of different sizes. It felt very soft between the fingers, and left a stain upon paper like Indian ink; but though washed with 24 ounces of water, still tasted acid. Half an ounce of it distilled in a retort yielded a drachm and an half of weak acetous mixed with a little sulphureous acid; the residuum was a black coal, which by calcination in an open fire for a quarter of an hour, yielded 25 grains of white ashes, consisting of selenite, calcareous earth, and magnesia. A drachm of it digested with nitrous acid, which was afterwards distilled from it, and then diluted with distilled water and filtered, yielded a few crystals, which appeared to be genuine salt of tartar, an insoluble selenite being left behind. On rectifying the vitriolic acid freed from the black matter and diluted with eight ounces of water, nine ounces of sulphureous acid were first obtained, after which followed an ounce of acid rather high-coloured, and then the vitriolic acid quite colourless. It now weighed only $19\frac{1}{4}$ ounces, and its specific gravity was but 1.723, while that of the acid originally employed had been 1.989.

On repeating the process with six pounds of spirit of wine to two of oil of vitriol, the first 12 ounces that came over were spirit of wine almost totally unchanged; then two ounces smelling a little of ether; and afterwards two pounds, of which about one third were ether. When about five pounds had been drawn off, the distilling liquor began to smell sulphureous; and after nine ounces more had been drawn off, the

frothing up of the matter in the retort obliged him to put an end to the operation. The acid was then filtered through pounded glass as before, and afterwards committed to distillation. The three first ounces were a weak sulphureous acid; then followed an ounce more concentrated, and of a red colour; then another of a yellowish cast; after which the rest of the acid came over quite colourless. The whole weighed 27 ounces, and the specific gravity of it compared with distilled water was as 1.667 to 1.000.

Ether is the lightest of all known fluids, except air; and is so volatile, that *in vacuo* its boiling point is 20° below 0° of Fahrenheit's thermometer. If a small quantity is poured out on the ground, it instantly evaporates, diffusing its fragrance all through the room, and scarce perceptibly moistening the place on which it fell. It difficultly mixes with water, as being of an oily nature: ten parts of water, however, will take up one part of ether. Its great volatility renders it serviceable in nervous diseases, and removing pains, when rubbed on with the hand, and kept from evaporating immediately. By spontaneous evaporation, it produces a great degree of cold. (See EVAPORATION and CONGELATION). The most extraordinary property, however, is, that if gold is dissolved in aqua-regia (see *Metallic Substances*, below), and ether added to the solution, the gold will leave the acid and permanently unite with the ether. The exceeding great volatility of ether renders it very easily inflammable even on the approach of flame; and therefore it ought never to be distilled, or even poured from one vessel to another, by candle-light. If a less quantity of the vitriolic acid is added to the spirit of wine than what is sufficient to produce ether, the product is called *spiritus vitrioli dulcis*. The following experiment made by Wallerius, induced him and others to think, that the vitriolic acid was convertible into the nitrous.

"Some salt of tartar (says he) being mixed with the dulcified spirit of vitriol, or perhaps with the ether (for the author expresses himself a little ambiguously), the full bottle stopp'd with a cork, tied over with bladder, and laid on its side; on standing for four months, the greatest part of the spirit was found to have escaped, and the salt was shot into hexangular prismatic crystals resembling nitre. It tasted strongly of the spirit, but had no other particular taste. Laid on a burning coal, it crackled, exploded with a bright flash, and flew into the air. He afterwards found, that by adding to the spirit a drop or two of any acid, the salt crystallizes the sooner; that in this case it has a sourish taste, but in other respects is the same with that made without acid. This salt-petre (says the author) promises, from the violence of its explosion, to make the strongest gun-powder in the world, but a very dear one. Though the experiment should not be applicable to any use in this way, it will probably contribute to illustrate the generation of nitre: as it palpably shows nitre, that is, the acid or characteristic part of nitre, produced from the vitriolic acid and phlogiston."

We cannot here help again regretting that chemists of superior abilities should sometimes leave very important discoveries only half finished, so that chemists of an inferior rank know not what to make of them. Had Wallerius,

Wallerius, who seems more than once to have been in possession of this salt, only poured on it a few drops of oil of vitriol, the peculiar colour and smell of the fumes must have been a much more convincing proof of the reality of the transmutation than that of mere deflagration; because the latter can be otherwise accounted for.

722
Violent ex-
plosions
from the
application
of heat.

It is certain, that many substances, water itself not excepted, will explode with great violence if suddenly heated beyond what they are able to bear. If spirit of wine is confined in a close vessel, it will also by means of heat burst it as effectually as water; and as the vapours of this substance are inflammable, the explosion will be attended with a flash if any flame is near. In like manner ether, on the approach of a candle, takes fire, and goes off in a flash like lightning; but this happens, not from any thing nitrous, but from its great volatility and inflammability. If therefore the vapours of the ethereal liquor are confined, and heat is applied suddenly to the containing vessel, their great volatility will cause them make an instantaneous effort against the sides of it, which increasing with a swiftness far beyond that of aqueous or spirituous vapours, will make a much quicker as well as a much stronger explosion than either of them; and if a flaming substance is near, the explosion will be attended with a bright flash like that of the ether itself.

In the experiment now before us, the salt tasted strongly of the spirit, or ether, from which it was made. The spirit was therefore confined in the crystals of salt; and his volatile liquor, which, even under the pressure of the atmosphere, boils with the heat of 100° of Fahrenheit, was, in a confined state, subjected to the heat of a burning coal; that is, to more than ten times the degree of heat necessary to convert it into vapour. The consequence of this could be no other, than that the particles of salt, or perhaps the air itself, not being capable of giving way soon enough to the forcible expansion of the ether, a violent explosion would happen, and the salt be thrown about; which accordingly came to pass, and might very reasonably be expected, without any thing nitrous contained in the salt.

2d 722
Cavallo's
method of
purifying
ether.

Mr Cavallo describes an easy and expeditious method of purifying ether, though a very expensive one; as out of a pound of the common kind scarce three or four ounces will remain of that which is purified. The method of purifying it, he says, was communicated to him by Mr Winch chemist in London, and is to be performed in the following manner. "Fill about a quarter of a strong bottle with common ether, and pour upon it twice as much water; then stop the bottle and give it a shake, so as to mix the ether for some time with the water. This done, keep the bottle for some time without motion, and the mouth of it downwards, till the ether be separated from the water, and swims above it; which it will do in three or four minutes. Then opening the bottle with the mouth still inverted, let the greatest part of the water run out very gently; after this, turn the bottle with the mouth upwards; pour more water upon the ether, shaking and separating the water as before. Repeat this operation three or four times; after which the ether will be exceedingly pure, and capable of dissolving elastic gum, though it could not do so before."

As great part of the ether undoubtedly remains mixed with the water after this process, our author remarks, that it might be worth while to put the water into a retort and distil the ether from it, which will come sufficiently pure for common use. He observes also, that "it is commonly believed that water combines with the purest part of the ether when the two fluids are kept together; though the contrary seems to be established by this process. According to Mr Wastrumb, we may obtain from the residuum of vitriolic ether a resin containing vitriolic acid, vinegar, Glauber's salt, selenite, calcareous earth, silice, iron, and phosphoric acid.

Nitrous
Acid and its
Combina-
tions.

§ 2. Of the NITROUS Acid and its Combinations.

THIS acid is far from being so plentiful as the vitriolic. It has been thought to exist in the air; and the experiments of Mr Cavendish have shown, that it may be artificially composed, by taking the electric spark in a mixture of dephlogisticated and phlogisticated air. See AEROLOGY, n° 77.

With regard to the preparation of nitre, Dr Black observes, that it is made in great plenty in the more southern parts of Europe; likewise in the southern parts of Persia, in China, the East Indies, and in North America. We have had no accounts of the manner in which it is prepared in the East Indies, no person on the spot having taken particular notice of the manufacture. The general account is, that it is obtained from the soil of certain districts which are called *saltpetre grounds*; where the soil is very cold, barren, and unhealthy. The salt is there ready formed by nature. It is only necessary to gather large quantities of the earth, and to put it into a cavity through which a great quantity of water is poured, which dissolves the nitre; and the lixivium runs into an adjacent pit, out of which it is lifted in order to be evaporated and obtained in the form of crystals. This account, however, has been thought unsatisfactory; because there is hardly any part of Europe in which it is found in this manner. It is discovered indeed in some very large districts in Poland, particularly in Podolia, where the country is flat and fertile, and had been once very populous, but is now in a great measure deserted. It is there obtained from tumuli or hillocks, which are the remains of former habitations; but these are the only places in which it is found in any considerable quantity. In Spain, it is said that the inhabitants extract it from the soil after a crop of corn. It has been found in America in lime-stone grounds, in the floors of pigeon-houses, tobacco-houses, or the ruins of old stables, where a number of putrefying vegetables were once collected. In general, however, it is extracted from artificial compounds or accidental mixtures, where animal and vegetable substances have been fully putrefied by being exposed to the air with any spongy or loose earth, especially of the calcareous kind, and open to the north or north-east wind, and more or less covered from the heat or rains. This last particular is absolutely necessary to its formation in any quantity; for the heat, by evaporating the moisture too much, prevents it from being produced, and the rains wash it away after it is already made. Cramer, an author of the greatest credit, informs us in his *Docimaestics*, that he made a little hut exposed to the fresh air of the

country, with windows to admit the winds. In this he put a mixture of garden mold, the rubbish of lime, and putrid animal and vegetable substances. This he frequently moistened with urine; and in a month or two found his composition very rich in nitre, yielding at least one-eighth part of its weight.

It is manufactured in Europe by making artificial compounds with less trouble. In Hanover it is got by collecting the rakings of the streets; which are built up into mud-walls that are allowed to remain a certain time, when the surface is found covered with a white saline efflorescence. A person is employed to scrape this off; and putting it into a vessel, it is washed with water to dissolve the nitre, and the remaining earthy matter is again plastered on the mud-walls, and fresh matter brought from the streets to renew them occasionally: and by this simple method a considerable quantity is obtained. In Germany the peasants are directed by law to build mud-walls of this kind with the dung and urine of animals, and some straw. After they have stood for some time, and the vegetable and animal substances are rotten, they afford a considerable quantity of nitre. In France it is obtained from accidental collections of this kind; as where loose earth has been long exposed to the contact of animal substances, as the ruins of old stables, pigeon-houses, &c. Sometimes from the mould upon the ground where dunghills have been lying. A particular set of people go about in search of these materials; and when, by making a small essay, they find that they will turn to account, they put the materials into a large tub with a perforated bottom, and another which is water-proof put below it. Some straw is interposed betwixt the two; and on pouring water upon the materials, it soaks through them, undergoes a kind of filtration in passing through the straw, and is then drawn off by a cock placed in the under-tub, and boiled to a proper consistence for crystallization. The crystals are at first brown and very impure, but by repeated dissolution and crystallization become pure and white.

From these particulars relating to the history of salt-petre, Dr Black concludes, that it is not properly a fossil, being produced at the surface of the ground. Margraaf discovered a small quantity of it in the analysis of some of the waters about Berlin, and others have found it in the wells about some great cities: but no true nitre has ever been found in springs; so that this nitrous salt may be supposed to have derived its origin from the quantity of putrid matters with which all cities abound. All rich and fertile soils are found to contain it; and in the hot countries, where the products of nature are numerous, and putrefaction carried on very fast, they are often very rich in nitre. This may happen in some places from the conflux of waters; which remaining for some time on the surface, and afterwards exhaling, left the saline particles behind.

On the whole, Dr Black concludes, that neither nitre nor its acid does exist in the air, because it might easily be detected there; though many have embraced this opinion from its being usually found at the surface of the ground. He is of opinion, that it is the effect of the last stage of putrefaction of animal and vegetable substances; and it is never to be found except where these or their effluvia are present, and

never till the putrefaction is complete. It has been a matter of dispute, whether it existed in those matters before the process of putrefaction, or was produced by it. But it is pretty certain, says the Doctor, that it originated in them; for the sun-flower, tobacco, and other plants, are found to contain it before putrefaction: and some have even asserted, that plants placed in the earth, deprived of all its saline substances, will yield it. The compositions recommended by Cramer are the fittest for producing a complete degree of putrefaction, provided they contain a moderate degree of humidity, and that the quantity exposed to the air be defended from too great a heat by the sun, which would dry up its moisture; and likewise from too great a degree of cold, which likewise checks fermentation. The importance of the calcareous earth in such a composition would likewise favour the conclusions just now drawn; for the most remarkable effect of this earth is to promote and perfect the putrefaction of these substances. It would seem, therefore, that the true secret of the production of nitre is to mix properly together animal and vegetable substances with earth, particularly of the calcareous kind; exposing them to the air with a moderate degree of humidity, sufficient to promote their putrefaction in the most effectual manner; and when the putrefaction is carried to the utmost height, we may then expect that nitre will be produced.

The distinguishing characteristic of the nitrous acid is its great disposition to unite with the phlogiston; and, when so united, first to become exceedingly volatile, and at last to be dissipated in a very white bright flame: this is called its *detonation* or *deflagration*. In the strongest state in which this acid is procurable in a liquid form, it is of a reddish yellow colour, and continually exhales in dense, red, and very noxious fumes; and in this state is called *smoking*, or, from its inventor, *Glauber's*, spirit of nitre.

I. To extract the Nitrous Acid by means of the Vitriolic.

Into a glass retort put two pounds of good salt-petre, and pour upon it 18 ounces of concentrated oil of vitriol; set the retort in a sand heat, and lute on a large receiver with the composition already recommended, for resisting acid fumes; the mixture will grow very warm, and the retort and receiver will be filled with red vapours. A small fire is then to be kindled, and cautiously raised till no more drops will fall from the nose of the retort. What comes over will be a very strong and smoking spirit of nitre.

In this process, the nitrous acid is generally mixed with part of the vitriolic which comes over along with it, and from which it must be freed if designed for nice purposes. This is most effectually done by dissolving in it a small quantity of nitre, and redistilling the mixture. The vitriolic acid which came over in the first distillation is kept back by the nitre in the second, combining with its alkaline basis, and expelling a proportionable quantity of the nitrous acid.

We have here directed the pure vitriolic acid to be used, in order to expel the nitrous one; but for this purpose any combination of the vitriolic acid with a metallic or earthy basis may be used, though not with equal advantage. If calcined vitriol is made use of,

tions.

as much phlogiston is communicated by the calx of iron contained in that salt as makes the nitrous acid exceedingly volatile, so that great part of it is lost. If calcined alum, or selenite, is made use of, the vitriolic acid in these substances immediately leaves the earth with which it was combined, in order to unite with the alkaline basis of the nitre, and expels its acid: but the moment the nitrous acid is expelled from the alkali, it combines with the earth which the vitriolic acid had left; from which it cannot be driven without a violent fire; and part of it remains obstinately fixed, so as not to be expelled by any degree of heat. Hence the produce of spirit, when nitre is distilled with such substances, always turns out considerably less than when the pure vitriolic acid is used. Alum is preferable to selenite, for the purposes of distilling spirit of nitre; because the acid does not adhere so strongly to argillaceous as to calcareous earth.

According to Weigleb, the nitrous acid may be expelled not only by clay, gypsum, and other substances containing the vitriolic acid, but even by various kinds of vitrifiable earth. Clean pebbles, quartz in the form of sand, pieces of broken china and stone ware, powdered glass, &c. mixed with nitre in the proportion of six to one, always expel the acid, though imperfectly. In France the acid is always extracted by means of clay.

The reason of these decompositions is, that the alkaline basis of the nitre attracts the siliceous earth, whose fixedness in a vehement fire gives it an advantage over the volatile nitrous acid, in the same manner that the weak acid of phosphorus or arsenic will also expel it by reason of their fixedness in the fire.

Even spirit of salt, according to Margraaff's experiments, may be used for distilling the spirit of nitre. That celebrated chemist informs us, that on distilling nitre with eight or nine times its quantity of strong marine acid, a spirit comes over which consists chiefly of the nitrous acid, but has also some portion of that of sea-salt. The reason of this is shown in Mr Kirwan's experiments on chemical attractions*. In the present case, however, the decomposition may be facilitated by the strong attraction of the nitrous acid for phlogiston; for it is well known, that on mixing the nitrous and marine acids together, the latter is always dephlogisticated. It seems therefore that in this case a double decomposition takes place, the nitrous acid uniting itself to the phlogiston of the marine, and the latter attaching itself to the alkali of the nitre.

Spirit of nitre is very useful in the arts of dyeing and refining, where it is known by the name of *aqua fortis*; and therefore an easy and cheap method of procuring it is a valuable piece of knowledge. Many difficulties, however, occur in this process, as well as that for the vitriolic acid. Oil of vitriol, indeed, always expels the nitrous acid with certainty; and on distilling the mixture, a spirit of nitre arises: but if a glass retort is used for the purpose of distilling this acid, the quantity of residuum left in distillation is so great, and so insoluble in water, being no other than vitriolated tartar, that the retort must always be broken in order to get it out; and the produce of spirit will scarce afford the breaking a retort. If earthen retorts are made use of, they must certainly be of that kind called stone-ware, and the price of them will be

very little if at all inferior to that of glass. Iron pots are said to be made use of in the distillation of common aquafortis in large quantities; but they have the great inconvenience of making a quantity of the acid so volatile, that it not only will not condense, but spreads its suffocating vapours all around in such a manner as to prove very dangerous to those who are near it. If an iron vessel, therefore, is thought of for the purpose of distilling aquafortis, it will be proper at least to attempt luting over the inside with a mixture of gypseous earth and sand, to prevent as much as possible the acid from attacking the metal.

Dephlogisticated spirit of nitre is obtained by distilling the smoking kind with a gentle heat, until what remains is as colourless as water. It is distinguished by emitting white and not red fumes like the other kind, when set in a warm place. It must be kept constantly in the dark, otherwise it will again become phlogisticated, and emit red vapours by the action of the light; the same thing will also take place if it be heated with too violent a fire.

II. To procure the Nitrous Acid by means of *Arsenic*.

Pulverise equal quantities of dried nitre and white crystalline arsenic; mix them well together, and distil in a glass-retort with a fire very cautiously applied; for the arsenic acts on the nitre with such a violence, and the fumes are here so volatile, that unless great care is taken, a most dangerous explosion will almost certainly happen. As, in this case, the nitrous fumes arise in a perfectly dry state, some water must be put into the receiver, with which they may unite and condense. The aquafortis so produced will have a blue colour, owing to the inflammable principle separated from the arsenic, by which its extreme volatility is likewise occasioned. If this blue aquafortis is exposed to the air, its colour soon flies off. If instead of the white arsenic we employ the pure arsenic acid, the distilled liquor will have no blue colour.

Nitrous Acid COMBINED,

I. *With Vegetable fixed Alkali*. This salt, combined with the nitrous acid to the point of saturation, regenerates nitre. It is observable, however, according to Neumann, that there is always some dissimilarity between the original and regenerated nitre, unless quicklime is added. The regenerated salt, he says, always corrodes tin, which the original nitre does not; owing probably to a quantity of phlogisticated acid remaining in it. Boiling with quicklime deprives it of this quality, and makes it exactly the same with original nitre.

II. *With Fossile alkali*. The neutral salt arising from a combination of the nitrous acid and fossile alkali is somewhat different from common nitre; being more difficult to crystallize, inclining to deliquesce in the air, and shooting into crystals of a cubical form, whence it gets the name of *cubic nitre*. Its qualities are found somewhat inferior to the common nitre; and therefore it is never made, unless by accident, or for experiments.

Nitre is one of the most fusible salts. It is liquefied in a heat much less than what is necessary to make it red; and thus remain in tranquil fusion, without swelling. If nitre thus melted be left to cool and fix, whe-

tions.

whether it has been made red-hot or not in the fusion, it coagulates into a white, semi-transparent, solid mass, called *mineral crystal*, having all the properties of nitre itself. By this fusion, Mr Beaumé observes that nitre loses very little, if any, of the water contained in its crystals, since the weight of mineral crystal is nearly the same with that of the nitre employed.

When nitre is kept in fusion with a moderate heat, and at the same time does not touch any inflammable matter, nor even flame, it remains in that state without suffering any very sensible alteration; but if it is long kept in fusion with a strong fire, part of the acid is destroyed by the phlogiston which penetrates the crucible; and hence the nitre becomes more and more alkaline.

743
Uses.

Nitre is of very extensive use in different arts; being the principal ingredient in gun-powder; and serving as an excellent flux to other matters; whence its use in glass making. (See GLASS.) It is also possessed of a considerable antiseptic power; whence its use in preserving meat, to which it communicates a red colour. In medicine, nitre is used as a diuretic, sedative, and cooler; but very often fits uneasy on the stomach. The resemblance of the crystals of nitre to those of Glauber's salt has sometimes been the occasion of dangerous mistakes. Dr Alexander mentions a swelling over the whole body of a woman, occasioned by her taking a solution of nitre instead of Glauber's salt. Two mistakes of the same kind we have also known. In one an ounce, and in the other upwards of two ounces, of nitre were swallowed. The symptoms occasioned were universal coldness and shivering, extreme debility and sickness at stomach, cold sweats, and faintings. Neither of the cases proved mortal. The cure was effected by cordials and corroborants.

744
Sal prunella.

A process has obtained a place in the dispensatories for a supposed purification of nitre by means of flower of brimstone. A pound of salt-petre is to be melted in a crucible, or small iron vessel; and an ounce of flowers of sulphur thrown upon it, by small quantities at a time: a violent deflagration ensues on each addition; and after the whole is put in, the salt is poured out in moulds, and then called *sal prunella*. It has been disputed whether the nitre was at all depurated by this process; Dr Lewis thinks it is not. From our own experience, however, we can affirm, that by this means a sediment falls to the bottom, which carries with it any impurities that may have been in the nitre, and leaves the fluid salt clear and transparent as water. This precipitate is probably no other than a vitriolated tartar formed by the union of the sulphureous acid and alkali of the nitre, which being less fusible than the nitre, subsides in a solid form and clarifies it.

745
Nitrous ammoniac.

III. *With Volatile Alkali*. The nitrous acid seems peculiarly adapted to an union with volatile alkali; saturating as much, or rather more of it than the strongest vitriolic acid is capable of doing. The product is a very beautiful salt, called *volatile nitre*, or *nitrous sal ammoniac*. It very readily dissolves, not only in water, but in spirit of wine, which distinguishes it from the vitriolic and common kind of sal ammoniac. It also requires less heat for its sublimation: indeed care must be taken not to apply too great a heat for this purpose, as

N 72.

the nitrous sal ammoniac has the property of deflagrating by itself without any addition of inflammable matter; and this it does more or less readily, as the volatile alkali with which it was made was more or less impure and oily.

The medical virtues of this kind of nitre have not been inquired into. It seems to have made the principal ingredient in the famous Dr Ward's white drop, which was celebrated as an antiscorbutic; with what justice, those who have tried it must determine.

IV. *With Calcareous Earths*. These the nitrous acid dissolves into a transparent colourless liquor; but for this purpose it must be very much diluted, or the solution will have a gelatinous consistence. This compound is not applicable to any useful purpose. It has a very acrid taste; and, if inspissated, attracts moisture from the air. If it is totally dried, it then resembles an earthy matter, which deflagrates very weakly. By distillation in a retort, almost all the acid may be expelled, and what little remains flies off in an open fire.

Mr Pott, who has particularly examined the combination of nitrous acid with quicklime, says that the acid suffered remarkable alterations by distillation from quicklime, and repeated cohobations upon it. By these experiments he obtained a salt more sensibly susceptible of crystallization and detonation, than what can be obtained by a single combination. From his experiments it would seem, that nitrous acid, by this treatment with quicklime, was capable of being entirely decomposed.

If a solution of chalk in the nitrous acid be evaporated to dryness, and then gently calcined, it acquires the property of shining in the dark, after having been exposed to the sun's rays, or even to the light of a candle. This substance, from its inventor, is called *Baldwin's phosphorus*; or, from its being necessary to keep it in a glass hermetically sealed, *phosphorus hermeticus*. (See EARTHS).

V. *With Argillaceous Earths and Magnesia*. All that is known concerning the combinations of nitrous acid with these earths is, that the first produce astringent, and the second purgative, compounds, similar to alum and Epsom salt, and which are not susceptible of crystallization.

VI. *With Gold*.—Till very lately, it has been the opinion of chemists, that the nitrous acid by itself was incapable of acting upon this metal.—Dr Brandt, however, produced before the Swedish academy of sciences, a solution of gold in the nitrous acid, obtained in parting, by that acid, a mixture of gold and silver.—The mixed metal was boiled with aquafortis in a glass body fitted with a head and receiver, the liquor poured off, and the coction repeated with fresh parcels of stronger and stronger nitrous spirits, till all the silver was judged to be extracted. The last parcel was boiled down till the matter at the bottom looked like a dry salt; on boiling this in fresh aquafortis in close vessels, as before, a part of the gold was dissolved, and the liquor tinged yellow. But though gold is by this means truly soluble in the nitrous acid, the union is extremely slight; the gold being not only precipitated on the addition of silver, but likewise spontaneously on exposure to the air.—Dr Lewis very justly observes, that this solution may have been often made unknown

unknown to the chemists who did so; and probably occasioned the mistakes which some have fallen into, who thought that they were in possession of aquafortis capable of transmuting silver into gold. Notwithstanding these authorities, Mr Kirwan is of opinion that the nitrous acid is in no case able to dissolve gold; the metal being only intimately mixed or diffused through it.

751
Silver.

II. *With Silver*.—Pure spirit of nitre will dissolve its own weight of silver; and shoots with it into fine white crystals of a triangular form, consisting of very thin plates joined closely one upon another. These crystals are somewhat deliquescent; of an extremely bitter, pungent, and nauseous taste; and, if taken internally, are highly corrosive and poisonous. They melt in a small heat, and form, on cooling, a dark-coloured mass still more corrosive, called *lunar caustic* or *lapis infernalis*. They readily dissolve in water; and, by the assistance of warmth, in spirit of wine. In the *Actæ Naturæ Curiosorum*, tom. vi. there is a remarkable history of silver being volatilized by its combination with the nitrous acid. Four ounces of silver being dissolved in aquafortis, and the solution set to distil in an earthen retort, a white transparent butter arose into the neck, and nothing remaining behind; by degrees the butter liquefied, and passed down into the phlegm in the receiver. The whole being now poured back into the retort, the silver arose again along with the acid. The volatilization being attributed to the liquor having stood in a laboratory where charcoal was bringing in, the experiment was repeated with a fresh solution of silver, and a little powdered charcoal, with the same event.

752
Lunar cau-
stic.

753
Colours
produced
by solution
of silver.

Solution of silver in the nitrous acid stains hair, bones, and other solid parts of animals, and different kinds of wood, of all the intermediate shades from a light brown to a deep and lasting black. The liquors commonly sold for staining hair brown or black, are no other than solutions of silver in aquafortis, so far diluted in water as not sensibly to corrode the hair.

It gives a permanent stain likewise to sundry stones; not only to those of the softer kind, as marble, but to some of considerable hardness, as agates and jaspers. The solution for this purpose should be fully saturated with the metal; and the stone, after the liquor has been applied, exposed for some time to the sun. M. du Fay observes (in a paper on this subject in the French memoirs for 1728), that if the solution be repeatedly applied, it will penetrate in the whitish agate, or chalcedony, about one-twelfth of an inch: that the tincture does not prove uniform, on account of the veins in the stone: that the colours, thus communicated by art, are readily distinguishable from the natural, by disappearing on laying the stone for a night in aquafortis: that, on exposing it to the sun afterwards for some days, the colour returns: that the solution gave somewhat different tinctures to different stones; to oriental agate, a deeper black than to the common chalcedony; to an agate spotted with yellow, a purple; to the jade stone, a pale brownish; to the common emerald, an opaque black; to common granite, a violet unequally deep; to serpentine stone, an olive; to marble, a reddish, which changed to purple, and fixed in a brown: that on slates, talcs, and amianthus, it had no effect.

VOL. IV. Part II.

If a solution of silver be diluted with pure water, a considerable quantity of pure mercury added, and the whole set by in a cold place; there will form by degrees a precipitation and crystallization resembling a little tree, with its root, trunk, and branches, called *arbor Diana* or the *philosophic silver tree*. Another kind of artificial vegetation may be produced by spreading a few drops of solution of silver upon a glass plate, and placing in the middle a small bit of any of the metals that precipitate silver, particularly iron. The silver quickly concretes into curious ramifications all over the plate.

Nitrous
Acid and
its Combi-
nations.
754
Arbor Dia-
na.

Like other metallic solutions, this combination of the nitrous acid with silver is decomposed by fixed and volatile alkalies, calcareous earths, and several metals, (see the *Table of Affinities*); but with several peculiar circumstances attending the precipitation. With metals, the silver is readily and copiously thrown down at first, but slowly and difficultly towards the end. The menstruum generally retains some portion of the silver, as the silver almost always does of the metal which precipitated it. For recovering the silver from aquafortis after parting, the refiners employ copper. The solution, diluted with water, is put into a copper vessel, or into a glass one with thin plates of copper, and set in a gentle warmth. The silver begins immediately to separate from the liquor in form of fine grey scales, or powder; a part of the copper being dissolved in its place, so as to tinge the fluid more or less of a bluish green colour. The plates are now and then shaken, that such part of the silver as is deposited upon them may fall off, and settle to the bottom. The digestion is continued till a fresh bright plate, kept for some time in the warm liquor, is no longer observed to contract any powdery matter on the surface; when the liquor is poured off, and the precipitate washed with fresh parcels of boiling water. It is observable, that though the acid in this process saturates itself with the copper, in proportion as it lets go the silver, yet the quantity of copper which it takes up is not near so great as that of silver which it deposits. One drachm of copper will precipitate three of silver, and saturate all the acid that held the three drachms dissolved.

Calcareous earths, as chalk or quicklime, throw down a part of the silver, but leave a very considerable part suspended in the liquor. If the earth be moistened with the solution into the consistence of a paste, and exposed to the sun, it changes its white colour to a dark purplish black; distinct characters may be exhibited on the matter, by intercepting a part of the sun's light by threads, slit paper, &c. placed on the outside of the glass. Culinary fire does not affect its colour: after the mass has been exsiccated by this, it changes as before, on exposure to the sun.

756

of a glass
by means
of the sun's
light.

Mild volatile alkaline spirits, added to a solution of silver, precipitate but little, and caustic volatile alkalies none. Pure fixed alkalies, and alkalies rendered caustic by quicklime, throw down the whole. Fixed alkalies impregnated with inflammable matter by calcination with animal coals, occasion at first a considerable precipitation; but if added to a larger quantity, take up great part of the metal again. Mr Margraff relates, that edulcorated calces of silver totally dissolve, both in a lixivium of these alkalies and in vo-

3 O

latile

Nitrous
Acid and
its Combi-
nations.

volatile spirits; and that the marine acid precipitates the silver from the volatile, but not from the fixed, alkaline solution. Kunckel reports, that the calx precipitated by volatile spirits made with quicklime, fulminates or explodes in the fire; and that by inspissating a solution of pure silver, melting the dry residuum, pouring it on spirit of urine supersaturated with salt, and setting the mixture in a gentle warmth, a blood-red mass is produced, so tough as to admit of being wound about the fingers.

757
Copper.

III. *With Copper.* The nitrous acid very readily dissolves this metal into a green-coloured and very caustic liquor. The solution, if properly evaporated, will crystallize; but the crystals are deliquescent, and therefore difficult to be preserved. The only use of this combination is for the preparation of the pigment called *verditer*. Of this there are two kinds, the blue and green. The blue is by far the brightest colour, and consequently the most valuable. It has been said that this is obtained by precipitating a solution of copper by any calcareous earth; and therefore is sold by the refiners, who have large quantities of solution of copper accidentally made. The solution is said to be precipitated by chalk, or whiting; and that the precipitate is the beautiful blue colour called *verditer*. By this method, however, only the green kind can be obtained. The blue we have found to be of a quite different nature, and formed by precipitation with a gentle heat from a solution of copper in volatile alkali. See the article COLOUR-MAKING.

759
Iron.

IV. *With Iron.* On this metal the concentrated nitrous acid acts very violently, and plentifully corrodes, but does not dissolve it; the calx falling almost as fast as dissolved; and when it is once let fall, fresh acid will not take it up again. If the acid was diluted at first, it takes up a considerable proportion, provided the metal be leisurely added. If the solution is performed with extreme slowness, the colour will be green; but if otherwise, of a dark red. It does not crystallize; and, if inspissated to dryness, deliquesces in the air.

760
Tin.

V. *With Tin.* Concentrated nitrous acid acts upon tin with great force, but only corrodes the metal into a white indissoluble mass. In order to obtain a perfect solution of tin in the nitrous acid, the metal must be put in by very little at a time, and a diluted aquafortis made use of. This solution has been considerably used in dyeing, and is remarkable for heightening red colours of all kinds; but the solution made with *aqua-regis* is preferable.

761
Lead.

VI. *With Lead.* Proof aquafortis, lowered with an equal quantity of water, dissolves about half its weight of lead. On diluting the solution with a large quantity of water, it turns milky, and deposits great part of the metal. The solution shoots, upon exhaling part of the menstruum, into small pyramidal crystals with square bases, of an austere sweet taste.

762
Quicksilver
supposed to
be extracted
from lead.

In the memoirs of the French academy for 1733, there is a particular account of an experiment, in which mercury is said to have been extracted from lead by dissolving it in the nitrous acid. During the dissolution, there fell a precipitate, which is plainly proved to be mercury, and was looked upon to be one of the constituent parts of the lead separated by this simple process: it seems probable, however, that the mercury

in this case had been contained in the aquafortis; for pure lead dissolved in pure aquafortis gives no such precipitate.

Nitrous
Acid and
its Combi-
nations.

The crystals of lead in the nitrous acid, when thrown into the fire, do not deflagrate as other combinations of this acid with metallic or saline bases; but crackle violently, and fly around, with great danger to the by-standers. If they are rubbed into very fine powder, they may then be melted without any danger. By repeated dissolutions in fresh aquafortis, they at last form a thick fluid like oil, which cannot be dried without great difficulty. This composition is not adapted to any particular use, and is a violent poison.

VII. *With Quicksilver.* Aquafortis, of such a degree of strength as to take up half its weight of silver, dissolves with ease above equal its weight of mercury into a limpid liquor, intensely corrosive and poisonous, which spontaneously shoots into white crystals. These crystals, or the solution exsiccated, and moderately calcined, assume a sparkling red colour; and are used in medicine as an escharotic, under the name of *red precipitate*. The precipitate has sometimes been given internally, it is said, in very large quantities; even a whole drachm at one dose. But this would seem incredible; and the present practice does not countenance the taking of red precipitate inwardly. This solution seems to have been what gave the efficacy to Ward's white drop.

763
Quicksilver.

764
Red precipitate.

When red precipitate is prepared in quantity, it is proper to distil the mercurial solution; because most of the aquafortis may then be saved. It is exceedingly pure, if by purity we mean its being free of any admixture of vitriolic or marine acid; but is considerably tainted with the inflammable principle of the mercury extricated during the dissolution. In consequence of this, it is very volatile and smoking; which has generally, though improperly, been taken as a sign of strength in the nitrous acid.

VIII. *With Bismuth.* This semimetal is very readily acted upon by the nitrous acid. Proof aquafortis dissolves about half its weight of bismuth. If the metal was hastily added, the solution proves of a greenish colour; if otherwise, it is colourless and transparent. Unless the acid was diluted with about an equal quantity of water, a part of the bismuth crystallizes almost as fast as it dissolves. The metal is totally precipitated both by fixed and volatile alkalies. The last, added in greater quantities than are sufficient for precipitation, take it up again. The liquor generally appears greenish; by alternate additions of the alkaline spirit and solution, it becomes bluish or purple. Fixed alkalies calcined with inflammable matter likewise dissolve the bismuth after they have precipitated it.

765
Bismuth.

The only use of this compound is for the precipitation, which is used as a cosmetic, under the name of *magistery of bismuth*. The common way of preparing this is by diluting the solution very largely with water, upon which it turns milky, and a fine white precipitate falls, which is to be welledulcorated with water, and is then employed as a cosmetic both in washes and pomatums.

766

Concerning the preparation of this cosmetic, Neumann observes, that there are sundry variations.—“Some (says he) take aqua-regia for the menstruum; and for the precipitant a solution of sea-salt, alkalies, spirit

Nitrous
Acid and
its Combi-
nations.

spirit of wine, &c. Some mix with the solution of bismuth a solution of benzoin in spirit of wine, and thus obtain a magistery compounded of bismuth and benzoin. Others add a solution of chalk to the metalline solution, and precipitate both together by alkalies. I have made trial with a good number of different precipitants; and found, that with common fixed alkali and caustic alkali, with watery and vinous alkaline spirits, the magistery was white, and in considerable quantity; the liquor, after the precipitation with volatile spirits, appearing blue. That oil of vitriol threw down a white precipitate very copiously: but that with spirit of salt, or spirit of vitriol, the precipitate was in very small quantity, in colour like the foregoing; distilled vinegar making no precipitation at all. Common rectified spirit of wine, and tartarized spirit, common water, and lime-water, gave white precipitates. Solutions of nitre, vitriolated tartar, sal mirabile, alum, borax, common salt, sal ammoniac, the combination of marine acid with calcareous earth, and terra foliata tartari, all precipitated the bismuth white. With a solution of gold in aqua-regia the magistery proved grey; with a solution of the same metal in aqua-regia made with spirit of salt, the precipitate was likewise grey, and in small quantity; with solution of copper in aquafortis, white, and in very small quantity, the liquor continuing blue; with solution of vitriol of copper, white; with solution of mercury sublimite, white and plentiful; with solution of iron in aquafortis, yellowish; with solution of lead in aquafortis, and of sugar of lead, white; with solution of zinc in aquafortis there was little precipitate; and with solutions of silver, tin, regulus of antimony, and of mercury, in the same acid, none at all."

767
Zinc.

IX. *With Zinc.* Upon this femimetal the nitrous acid acts with great violence than any other, and will forsake any other metallic substance for it. The whole is very soon dissolved into a transparent colourless liquor. The calces of flowers of zinc are likewise soluble in the nitrous acid; but neither the solution of the flowers, nor of the metal itself, has been yet found applicable to any useful purpose. Neumann remarks, that on extracting with nitrous acid the soluble parts of calamine, which is an ore of zinc, the solution, inspissated to dryness, left a reddish brown mass, which on digestion with spirit of wine exploded and burst the vessel.

768
Regulus of
antimony.

X. *With Regulus of Antimony.* The nitrous acid rather corrodes than dissolves this femimetal. The corroded powder forms a medicine formerly used under the name of *bezoar mineral*, but now disregarded.

769
Regulus of
cobalt.

770
Regulus of
cobalt, how
discovered
in ores.

XI. *With Regulus of Cobalt.* This femimetal dissolves readily in the nitrous acid, both in its metallic form and when reduced to a calx. The solution is of a red colour. Hence the nitrous acid furnishes means of discovering this femimetal in ores after strong calcination; very few other calces being soluble in the nitrous acid, and those that are not influencing the colour.

XII. *With Nickel.* This femimetal is easily dissolved by the nitrous acid into a deep green liquor; but neither this solution, nor indeed the femimetal of which it is made, has hitherto been found of any use.

XIII. *With Arsenic.* This substance is readily dissolved by the nitrous acid; which abstracts the phlogiston,

and leaves the pure arsenical acid behind. See below *Acid of Arsenic*.

XIV. *With Expressed Oils.* These, as well as all other fatty or unctuous substances, are considerably thickened and hardened by their union with the nitrous acid. There is only one preparation where this combination is applied to any use. It is the *unguentum citrinum* of the shops. This is made by adding to some quantity of melted hog's-lard a solution of quicksilver in the nitrous acid. The acid, though in a diluted state, and combined with mercury, nevertheless acts with such force on the lard, as to render the ointment almost of the consistence of tallow.

XV. *With Vinous Spirits.* If highly rectified spirit of wine and strong spirit of nitre are suddenly mixed together, the acid instantly becomes volatile, and is dissipated with great heat and effervescence in highly noxious red fumes. If the acid is cautiously poured into the spirit, in the proportion of five, six, or even ten parts of spirit to one of acid, and the mixture distilled in a glass retort set in a water-bath, an exceedingly fragrant and volatile spirit comes over, used in medicine as a diuretic and cooler, under the name of *spiritus nitri dulcis*. This liquor is not acid; nor has what remains in the retort any more the characteristics of nitrous acid, which seems to be entirely decomposed in this process. (See the following article.)

With the nitrous acid and spirit of wine, may also be made an exceedingly volatile liquor, called *nitrous ether*, to distinguish it from the vitriolic above mentioned. The proportions of nitrous acid and spirit of wine to each other for nitrous ether, are two of the acid by weight to three of the spirit. Dr Black's process for making it is as follows. Take four ounces of strong phlogisticated nitrous acid; and having cooled it by putting it into a mixture of salt and snow, or into water cooled very near the freezing point, by putting pieces of ice into it, he puts it into a phial, and pours upon it an equal quantity of water, likewise cooled very low, in such a manner that the water may float as much as possible on the surface of the spirit. Six ounces of strong spirit of wine are then put in, so as to float in like manner on the surface of the water; the phial is placed in a vessel containing cold water: and so great is the power of cold in restraining the action of bodies, that if the mixture was too cold, no ether would be produced; but at the temperature just mentioned, the ether begins to be formed in a few hours, with some little effervescence, and an expulsion of a small quantity of nitrous air. We must provide for the escape of this elastic fluid, by having an hole in the cork, or the vessel would be broken. The whole of the ether will be formed in a few days, and may be separated from the rest of the liquor by means of a funnel, shaped as in the margin.

To procure the nitrous ether in large quantities, Mr Woulfe recommends the following process. Put into a retort four pounds of nitre, then mix together four pounds of vitriolic acid, and three pounds five ounces of spirit of wine. These are poured on the nitre by adding only two ounces at a time: the vitriolic acid acting on the nitre, produces a sufficient degree of heat; and the acid of the nitre uniting with

the spirit, forms a nitrous ether, which flies off from the mixture, and is condensed in a number of vessels placed in cold water.—To obtain good nitrous ether readily, and at one distillation, Mr Dollfus advises to distil four parts of nitre of manganese, four of vitriolic acid, and eight parts of spirit of wine.

777
Inquiry in-
to the na-
ture of e-
ther.

Macquer supposes that ether is the most oily part or quintessence of spirit of wine. But it cannot be proved that ether contains any oil. And, besides, if this were the case, those acids which have the strongest attraction for water would produce the greatest quantity of ether; which is found not to be the case: and it is most probable that ether is produced by a combination of some part of the acid with a portion, particularly the inflammable part, of the spirit of wine; and it has been shown by chemical experiments, that every kind of ether contains a part of the acid employed. Dr Black himself has formed ether without any spirit at all, by exposing nitrous acid highly phlogisticated for some months to the light of the sun. This was owing to the attraction of the principle of inflammability; which it is well known that light has the power of affording to bodies that attract it with force.

Nitrous Acid DECOMPOSED,

778
Oils fired
by spirit of
nitre.

I. *By Essential Oils.* If equal quantities of strong nitrous acid and oil of cloves are poured into the same vessel, the mixture instantly takes fire; both acid and oil burning with great fury till only a light spongy coal remains. Dr Lewis observes, that this experiment does not always succeed, and that there are but few oils which can be fired with certainty, without attending to a particular circumstance first discovered by M. Rouelle, and communicated in the French Memoirs for the year 1747. "On letting fall into the oil equal its quantity of acid, the mixture effervesces, swells, and a light fungous coal arises: a little more of the acid poured upon this coal sets it instantly on fire. By this method almost all the distilled oils may be fired by spirit of nitre of moderate strength. Expressed oils also may be set on fire by a mixture of the nitrous acid and oil of vitriol; the use of which last seems to be to absorb the aqueous humidity of the spirit of nitre.

779
Nitre alkali-
zied.

II. *By Charcoal.* By this substance the nitrous acid cannot be conveniently decomposed, unless it is combined with an alkaline or metallic base. For the purpose of decomposing the acid, common saltpetre is most convenient. The proportions recommended by Dr Lewis for alkalizing nitre, are four ounces of the salt to five drachms of powdered charcoal. If these are carefully mixed, and injected by little and little into a tubulated retort made red hot, and fitted with a large receiver and a number of adapters, a violent deflagration will ensue on every addition, attended with a great quantity of air, and some vapours which will circulate for some time, and then condense in the vessels. This liquor is called *clyffus of nitre*. If sulphur is used instead of nitre, the clyffus is of a different kind, consisting of a mixture of the nitrous and vitriolic acids. The residuum, when charcoal is used, is a very strong and pure alkali; with sulphur it is vitriolated tartar. To prevent the loss occasioned by the violent deflagration, when this operation is performed in open vessels, Dr Black recommends to have the materials somewhat moist.

780
Clyffus of
nitre.

III. *By Vinous Spirits.* In the process already men-

tioned for making *spiritus nitri dulcis*, a total decomposition of the acid seems to take place: for neither the dulcified spirit itself, nor the acid matter left in the retort, show any signs of deflagration with inflammable matters, which is the peculiar characteristic of nitrous acid.

Mr Pott has given an analysis of the oleaginous residuum of the distillation. Distilled by a stronger fire, it gave over a yellow, acid, slightly empyreumatic spirit; which being saturated with fixed alkali, the liquor evaporated, and the dry neutral salt laid on burning coals, did not deflagrate. After this spirit arose a red empyreumatic oil; and in the bottom of the retort was left a shining black mass like soot; which, burnt in a crucible, left a white fixed earth, convertible by a vehement fire into glass. Another parcel of the above residuum was evaporated to the consistence of pitch. In this state it gave a yellow tincture to spirit of wine, flamed vividly and quietly on burning coals, and at last swelled up like bitumen. Another portion was saturated with alkaline ley, with which it immediately effervesced, and then evaporated as the former. It gave, as before, a yellow colour to rectified spirit of wine, and a much deeper yellow to dulcified spirit of nitre; and in the fire discovered no footstep of detonation. M. Macquer supposes this acid to have been not the nitrous, but the acetous, which enters into the composition of the spirit of wine; and his conjecture is now confirmed by late experiments.

§ 3. Of the MARINE Acid and its Combinations.

THIS acid is never, at least very rarely, found but in a state of saturation with the mineral alkali; in which case it forms the common salt used in food. Almost the only exception to this is human urine, and perhaps that of some other animals; for there the marine acid is found saturated, not with the mineral, but the common vegetable, fixed alkali. From being found in such plenty in the waters of the ocean, it has the name of *marine acid*.

It is commonly thought that this acid is no other than the vitriolic, somehow or other disguised by the inflammable principle; to which some have added another, called by them a *mercurial earth*.

The reasons given for this supposition, however, are but very slight, consisting chiefly in the resemblance between the volatile vitriolic acid and the marine, both in the white colour of their vapours, and likewise the great volatility of both. As to the existence of that principle called a mercurial earth, it hath never been proved; and, till that time, can never be allowed to be an ingredient in the composition of any substance whatever. As we do not remember to have read of any experiments where the marine acid was directly produced from that of vitriol, we shall content ourselves with relating one very remarkable fact which happened to fall under our own observation.

As vitriolated tartar, or Glauber's salt, when fused with charcoal-dust, is converted into an hepar sulphuris, attempts have been made on this principle to separate the pure alkali from the residuum of Glauber's spirit of nitre and spirit of salt. In an attempt of this kind, which, by the bye, proved unsuccessful, as all others of the same kind must do, 30 or 40 pounds

pounds of the mass for Glauber's salt were fused in a strong iron pot, with a sufficient quantity of common coal powdered and sifted. As the quantity of powdered coal was pretty large, the mass was thereby hindered from flowing into thin fusion; and, that the whole might be perfectly alkalifated, it was frequently stirred up with an iron ladle, and kept very intensely heated for some hours. The mass was now taken out by means of an iron ladle, and laid on a flat stone; and, as it was but half fluid, every ladleful concreted into a black irregular saline mass, which had the appearance of a cinder; but which, however, consisted of an hepar sulphuris mixed with some coal-dust. As there was a considerable quantity of this matter, and the ladlefuls were thrown at random above one another, it so happened, that between two or three of the pieces, a kind of chimney was formed, so that there being a small draught of air through the interstices, and the masses containing a quantity of coal-dust, the internal parts were in a state of ignition, while the external were quite cold. From these ignited places a white fume arose; which being collected on the colder masses, assumed the form of white flowers. These were found to be genuine sal ammoniac, composed of a volatile alkali and marine acid; both of which we have the greatest reason to think were produced at that very time, and that a double transmutation took place; namely, of the vitriolic acid into the marine, and of the fixed alkali into the volatile. Our reasons for being of this opinion are, 1. That the matter had been subjected to such an extreme and long continued heat, that, had any sal ammoniac been pre-existent in the mixture, it must have certainly been dissipated, as this salt always sublimes with a degree of heat below ignition. 2. Though the matter was taken out of the pot of a very intense red heat, so that the saline part was evidently melted, yet no ammoniacal fume issued from it at that time, nor till the masses had been for some time exposed to the air, and were become cool, excepting only those interstices where the air kept up a burning heat, by a small draught being formed from the situation of the saline masses. 3. In those ignited places, when cool, the fixed salt was entirely decomposed, neither alkaline salt, Glauber's salt, fixed alkali, nor sulphur remaining; but the whole was consumed to a kind of ferruginous ashes. We are therefore of opinion, that the marine acid and volatile alkali are, in some cases, mere creatures of the fire, and most commonly produced at the same time, from the slow combustion of mineral substances. Hence, where heaps of hot cinders are thrown out, small quantities of the true sal ammoniac are always formed, when the ignited ones happen to fall in such a manner as to occasion a small draught of air through them.

785
Dr Priest-
ley's obser-
vations on
marine a-
cid.

The marine acid, or spirit of salt, is weaker than either the vitriolic or nitrous; though Dr Priestley hath observed, that, when concentrated to the utmost degree, in which state it was perfectly invisible and elastic as air, it was then able to separate the nitrous acid from an alkali. In some other cases, too, it appears not only stronger than the nitrous, but even than the vitriolic; of which we shall take notice in course.—Mr Berthollet says, that he has been able also to procure the marine acid in a solid state, by distilling it in Mr Woulfe's apparatus, kept perfectly cool with ice.

The yellow colour of the marine acid is sometimes owing to iron, which may be precipitated from it by means of an alkali. In certain cases, however, it is observed to have a much darker and nearly a brown colour, without containing the smallest particle of this metal.—Mr Dollfus is of opinion, that the yellow colour of the marine acid is owing to a portion of dephlogisticated air which it generally contains. A pretty strong proof that it emits this kind of air indeed is, that a candle will burn longer in a bottle containing some marine acid, than it will in an equal quantity of common air.

Marine
Acid and
its Combi-
nations.

I. To procure the Marine Acid by means of the *Vitriolic*.

Put any quantity of sea-salt into a tubulated glass-⁷⁸⁶ retort, to which a large receiver is firmly luted, having a quantity of water in it, more or less as you want your spirit of salt to be more or less strong. Having placed your retort in a sand-bath, take of concentrated oil of vitriol half as much as you put salt into the retort. Through the aperture in the upper part of the retort, pour a small quantity of the vitriolic acid; a violent effervescence will immediately arise, and white vapours will ascend, and come over into the receiver. These vapours are the marine acid in its most concentrated state; and, as they are very greedy of moisture, they will unite with the water in a very short time, unless too much oil of vitriol is put in at once; in which case, part of them will be dissipated through the small hole in the receiver. When you perceive the first fumes condensed, add a little more oil of vitriol, taking care to stop the aperture of the retort as soon as you drop in the vitriolic acid, that the marine acid may not escape. Continue this by intervals, till your acid is all put in; and then make a very gentle fire, that the retort may be no warmer than the hand can bear. This degree of heat must be continued a long time, otherwise very much of the acid will be lost. To perform this operation perfectly, no more acid should be forced over, than what the water in the receiver can take up; and by this means the operator's patience will be rewarded with a vastly larger produce of acid than can be procured by hasty distillation. When the vapours become a little more fixed, a greater heat is necessary, but nothing equal to what the nitrous acid requires. For distilling spirit of salt, Mr Wiegleb recommends four pounds of oil of vitriol to six of common salt.—It may also be obtained from the bittern remaining after the crystallization of common salt, by adding one pound of oil of vitriol to five of bittern. It may even be obtained from this liquid by simple distillation without any additional acid; but a violent fire will then be necessary, and it is almost impossible to prevent the liquor from swelling and running over the neck of the retort in the beginning of the process.

Spirit of
sea-salt.

The marine acid cannot be procured by means of combinations of the vitriolic acid with metallic and earthy bases, as the nitrous is; for though, by means of calcined vitriol, for instance, the marine acid is effectually expelled from its alkaline basis, yet it immediately combines with the calx of iron left by the vitriolic acid, and not only adheres obstinately, but even sublimes the metal; so that what little spirit can be

787

Why distil-
lation of
sea-salt

peras does
not suc-
ceed.

ob-

Marine
Acid and
its Combi-
nations.

obtained, is never pure. This inconvenience is not so great when uncalcined copperas is made use of: for the marine acid has a very strong attraction to water; which partly dissolves its union with the metalline calx. If gypsum is used, instead of calcined vitriol, not a drop of spirit will be obtained. Alum and sal catharticus amarus answer better.

II. To procure the Marine Acid by means of the Nitrous.

788

Aqua regis.

Take equal quantities of sea-salt and Glauber's spirit of nitre; put the salt into a retort, and pour on it the nitrous acid; let them stand for 10 or 12 hours; then distil with a gentle heat; an acid liquor will come over, which is a compound of the nitrous and marine acids, called *aqua-regis*. When the distillation is finished, and the vessels cooled, pour back the distilled liquor on the mass which is left on the retort, and distil again: the second produce will be more of the nature of spirit of sea-salt than the former. Continue to do this, pouring the distilled liquor either on the mass left in the retort, or upon fresh sea-salt, till you observe that no nitrous acid arises. No experiments have been made on this spirit of salt, by which we can judge whether it is different from that procured by the vitriolic acid or not.

III. To procure the Marine Acid, by distilling Salt *per se*.

789

Spirit of salt
per se.

Put into a retort any quantity of common salt which has not been dried, and distil in a sand heat till nothing more will come over. In the receiver you will have a liquor considerably more acid than vinegar, in weight about the fourth part of the salt employed. On the dry salt left in the retort, pour some water, somewhat less in quantity than the liquor which came over. Let it stand till the salt has thoroughly imbibed the moisture, and then distil again. You will again have an acid, but weaker than the former. Repeat this six or seven times; after which you will obtain no more marine acid in this way. It has been thought that sea-salt was capable of total decomposition by means of moisture alone; but that is found to be a mistake. The reason of any acid being procurable in this way, is the impurity of the common salt, which is always mixed with a quantity of sal catharticus amarus, and of marine acid combined with magnesia, from which last it is separable by moisture. If a pure salt be formed by combining marine acid with salt of soda, no spirit will be obtained.

IV. To dephlogistate the Marine Acid.

790

Marine a-
cid de-
phlogisti-
cated by
that of
nitre or by
manganese.

The marine acid, when mixed either with that of nitre or with manganese, loses that peculiar smell by which it is usually distinguished, and acquires one much more volatile and suffocating. When mixed with the former, the compound is called *aqua-regia*; when subjected to the action of manganese, the product is called *dephlogistated spirit of salt*. The method of procuring this acid recommended by Mr Scheele is as follows: Mix common muriatic acid in any quantity with levigated manganese in a glass retort; to which lute on with blotting paper a receiver capable of containing about 12 ounces of water. Put about two drachms of liquid into it; and in about a quarter of an hour, or somewhat more, a quantity of elastic fluid, which is the

true dephlogistated spirit of salt, will pass over, and communicate a yellow colour to the air in the receiver; after which the latter is to be separated from the retort. If the paper has been closely applied, a quantity of the air will now rush out with some violence; a cork must therefore instantly be put into it, and another receiver applied, having in like manner two drachms of water in it, which will also be filled in a short time; and thus may several phials full of this aerial acid be procured in a short time. Care should be taken, that the retort be placed in such a manner as that any drops of liquid which chance to arise may fall down again into it. The water put into the receivers seems to condense the vapours of the marine acid; and it is most proper to use small receivers, on account of the great quantity of vapour which is lost at every operation.

The effects of this dephlogistated marine acid, which can scarcely be condensed into a liquid, are, 1. of dephlogistated spirit of salt. The lute is corroded in distillation, and the corks become yellow, as from aquafortis. 2. Paper coloured with lacmus becomes nearly white, as well as all vegetable red, blue, and yellow flowers; and the same change is likewise produced upon the green colour of vegetables; nor can any of these colours be recovered either by alkalies or acids. 3. Expressed oils and animal fats, exposed to the vapour, become as tenacious as turpentine. 4. Cinnabar grew white on the surface; and when it was washed, a pure solution of corrosive sublimate was obtained; but sulphur was not changed. 5. Green vitriol became red and deliquescent; but white and blue vitriol remained unchanged. 6. Iron filings were dissolved; and on evaporating the solution to dryness, common muriatic acid was obtained by distillation with marine acid. 7. In like manner all the metals, even gold itself, were dissolved; and by precipitation with volatile alkali, the solution of gold yielded aurum fulminans. 8. The caustic volatile alkali produced a white cloud, and emitted a number of air-bubbles, which on bursting discharged an elastic vapour. 9. Fixed alkali was changed into common salt, which decrepitated in the fire. 10. Arsenic became deliquescent, insects died, and fire was instantaneously extinguished in the vapour.

These phenomena proceed from the strong attraction of dephlogistated marine acid for the phlogiston it has lost; and which is one of the essential parts of it, without which it can scarce at all be condensed into a liquor. "Perhaps (says Mr Scheele) Stahl obtained such a dephlogistated muriatic acid by means of iron; and from the yellow colour of the cork was led to suppose that the muriatic acid had been changed into the nitrous. If you make a mixture of manganese, muriatic acid, or diluted vitriolic acid, and alcohol; and after some days digestion distil it by a gentle fire, no effervescence ensues: but the spirit of wine goes over; and, what is very remarkable, has a strong smell of nitrous ether.

A new salt has been produced by Mr Bertholet from the union of dephlogistated spirit of salt with vegetable alkali. This appears to be of the nitrous kind, as having a cool taste and detonating strongly in the fire. The compound was in very small quantity, and seemed to require more pure air for its composition than an equal bulk of acid. The greatest part of the salt produced was the common salt of Sylvius, or digestive salt, formed by a combination of the phlogistated marine

nations.

rine acid with alkali. Six parts of the dephlogisticated acid are required to give their air to one of the salt. When the fixed alkali is employed, some of the dephlogisticated acid escapes with the pure air; and in general, when not exposed to a bright heat, the salt we speak of is formed. Some of the dephlogisticated acid remains in its proper form after the salt is made, and may be separated by the volatile alkali. It is to be observed, that if the caustic alkali be employed, and the solution much concentrated, even though not under the influence of a bright light (for it is the light which produces the extrication of the dephlogisticated air*), a great effervescence will ensue, and a quantity of dephlogisticated air escape; whence, of consequence, little salt can be obtained.

* See Ac-
rology, n° 36,
et seq.

This salt is soluble in greater quantity in hot than cold water; and not only detonates like nitre, but with much greater violence. The reason is, that, like nitre, it not only contains dephlogisticated air, but has it in greater quantity; an hundred grains of salt giving 75 of air. Attempts have been made to procure gunpowder by means of this salt, but as yet they have been attended with little success.

The other properties of this salt as yet discovered are, that it shoots into rhomboidal crystals; it does not precipitate mercury, silver, or lead, from their solutions in nitrous acid; and it gives out its air again in such a pure state as scarcely to be paralleled in any other substance.

With the mineral alkali the dephlogisticated acid forms a deliquescent salt, soluble in spirit of wine; and which, even in a fluid state, detonates with burning charcoal. With lime, when so far quenched that the air in its interstices is separated, the dephlogisticated acid unites but weakly. It may be recovered from the lime, however, provided the light be obscure, with very little loss, and almost unchanged.

Marine Acid COMBINED,

794
Sal digesti-
vus sylvii.

I. *With Vegetable Fixed Alkali.* This combination is accidentally formed after the distillation of volatile salts, by means of salt of tartar (see *Alkaline Salts*). It was formerly known by the name of *sal digestivus Sylvii*; and a process for making it was inserted in the dispensatories, under the name of *spiritus salis marini coagulatus*; but as it has been found to possess no virtues superior, or even equal, to common salt, it is fallen into disuse.

The crystals of this kind of salt are not cubical, like those of common salt, but parallelipeds, and if thrown into the fire crack and leap about with violence. They are soluble in greater quantity by hot water than cold; and therefore are crystallized by evaporating the solution to a pellicle, and then letting it cool.—It is very remarkable, that though by a direct combination of vitriolic acid with vegetable fixed alkali, the salt called *vitriolated tartar* is formed; yet if this alkali is once saturated with spirit of salt, so as to form a *sal digestivus*, upon the decomposition of this salt by means of oil of vitriol, the residuum of the distillation will not be a vitriolated tartar, but a salt easily soluble in water, and which bears a strong resemblance to Glauber's salt. Whether, by means of spirit of sea-salt, the vegetable alkali could be converted into the mineral, or salt of soda, is a question well worthy of being solved.

II. *With Mineral Alkali.* This combination is the common alimentary salt, and is never made but for experiment's sake; as the marine acid cannot be had but from sea-salt. For the extraction of this salt from seawater, see the article *SALT*.

III. *With Volatile Alkali.* The produce of this combination is the common sal ammoniac, which is used in different arts, and which has the property of making tin unite very readily with iron and copper, so is much used by copper-smiths and in the manufactory of tinned iron.

Sal ammoniac is usually sold in large semi-transparent cakes, which are again capable of being sublimed into masses of the like kind. If they are dissolved in water, the salt very easily shoots into small crystals like feathers. Exposed to a moist air, it deliquesces. It is one of the salts which produces the most cold by its solution; so as to sink the thermometer 18 or 20 degrees, or more, according to the temperature of the atmosphere. According to Mr Gellert, a solution of sal ammoniac has the property of dissolving resins. According to Neumann, the volatility of sal ammoniac is so much diminished by repeated sublimations, that at last it remains half fluid in the bottom of the subliming vessel. In its natural state, it sublimes with a degree of heat necessary to melt lead. Pott says, that a small quantity of sal ammoniac may be produced by distilling sea-salt with charcoal, or with alum, or by distilling marine acid with Armenian bole. The same author affirms, that the inflammability of sulphur is destroyed by subliming it with twice its quantity of sal ammoniac.

The method of making this salt was long unknown; and it was imported from Egypt, where it was said to be prepared by sublimation from foot alone, or from a mixture of sea-salt, urine, and foot. That it should be produced from foot alone is very improbable; and the other method, from the known principles of chemistry, is absolutely impossible. The composition of this salt, however, being once known, there remained no other desideratum than a method of procuring those component parts of sal ammoniac sufficiently cheap, so as to afford sal ammoniac made in Britain at a price equally low with what was imported. The volatile alkali is to be procured in plenty from animal substances or from foot; and the low price of the vitriolic acid made from sulphur affords an easy method of decomposing sea-salt, and obtaining its acid at a low rate. A sal-ammoniac work has, accordingly, been established for several years past in Edinburgh: the principal material made choice of for procuring the volatile alkali is foot; and though no persons are admitted to see the work, the large quantities of oil of vitriol brought into it, and the quantities of genuine *sal mirabile* which are there made, evidently show that the process for making sal ammoniac also produces Glauber's salt, by the decomposition of common salt by means of vitriolic acid. The method of conducting the process is unknown; but it is plain that there can be no other difficulty than what arises from the volatility of the vapours of the alkali and of the marine acid. In the common way of distilling those substances, a great part of both is lost; and if it is attempted to make sal ammoniac by combining these two when distilled by the common apparatus, the produce

How made.

Marine
Acid and
its Combi-
nations.

duce will not pay the cost; a little ingenuity, however, will easily suggest different forms and materials for distilling-vessels, by which the marine acid and volatile alkali may be united without losing a particle of either.

If a solution of vitriolic or Glauber's secret sal ammoniac is mixed with sea-salt, the vitriolic acid seizes the alkaline basis of the sea-salt, and expels the marine acid; which immediately unites with the volatile alkali left by the vitriolic acid, and forms a true sal ammoniac. If this solution is now evaporated to dryness, and the saline mass sublimed, the sal ammoniac rises, and leaves a combination of vitriolic acid and mineral alkali at the bottom. This fixed mass being dissolved, filtered, and evaporated, affords Glauber's salts. This has sometimes been thought a preferable method of making sal ammoniac, as the trouble of distilling the marine acid was thereby prevented; but it is found vastly inconvenient on another account, namely, that when sal ammoniac is mixed with any fixed salt, it is always more difficult of sublimation, and a part of it even remains entirely fixed, or is destroyed. The mass of Glauber's salt also, by reason of the inflammable and oily matter contained in impure volatile alkalies, is partly changed into a sulphureous mass, so that the solution refuses to crystallize; at least the operation is attended with intolerable trouble.

797
Fixed sal
ammoniac.

IV. *With Earths.* The combinations of this acid with earths of any kind have never been found applicable to any purpose, and therefore they are seldom made or inquired into. The combination with calcareous earth is indeed pretty frequently made accidentally, in the distillation of volatile alkali from sal ammoniac by means of chalk or quicklime. When melted in a crucible and cooled, it appears luminous when struck, and has been called *phosphorus scintillans*. See EARTHS.

798
Phospho-
rus.

799
Solution of
gold in spi-
rit of salt.

V. *With Gold.* The marine acid has no action on gold in its metallic state, in whatever manner the acid be applied; but if the metal is previously attenuated, or reduced to a calx, either by precipitation from aqua regis or by calcination in mixture with calcinable metals, this acid will then perfectly dissolve, and keep it permanently suspended. Gold, precipitated from aqua regis by fixed alkalies, and edulcorated by repeated ablutions, may be dissolved even in a very weak spirit of salt by moderate digestion. This solution appears of the same yellow colour as that made in aqua regis; gives the same purple stain to the skin, feathers, bones, and other solid parts of animals; the same violet stain to marble; and strikes the same red colour with tin. Even when common aqua-regia is made use of for the menstruum, it seems to be chiefly by the marine acid in that compound liquor that the gold is held in solution. In distillation the nitrous acid arises, and the marine acid remains combined with the gold in a blood-red mass, soluble, like most of the combinations of metallic bodies with this acid, in spirit of wine. If, towards the end of the distillation, the fire is hastily raised, part of the gold distils in a high saffron-coloured liquor; and part sublimes into the neck of the retort in clusters of long slender crystals of a deep red colour, fusible in a small heat, deliquating in the air, and easily soluble in water. By repetitions of this process the whole of the gold may be elevated, except a small
N^o 72.

quantity of white powder whose nature is not known. —This red sublimate of gold is said to be easily fusible with the heat of one's hand, and to be shown by the Papists for the blood of St Januarius; the sublimate contained in a phial, being warmed by the hands of the priests who hold it, constitutes the miracle of that saint's blood melting on his birth-day.

VI. *With Silver.* Strong spirit of salt corrodes leaf-silver into a white powder, but has no effect on filings or larger masses of the metal. If applied in the form of vapour to masses of silver, and strongly heated at the same time, it readily corrodes them. Thus, if filings, grains, or plates, of silver are mixed with about twice their weight of mercury sublimate, and exposed to a moderate fire, in a retort, or other distilling vessel, a part of the marine acid in the sublimate will be separated and unite with the silver, leaving the mercury to arise in the form of mercurius dulcis. Marine acid is commonly supposed to be incapable of dissolving silver into a liquid state; but Henckel relates, that if red silver ore, which consists of silver intimately mixed with red arsenic, be digested in spirit of salt, the silver will be extracted and kept permanently dissolved.

The combination of marine acid with silver is called *Luna cornea*. The most ready way of preparing it is by dissolving silver in the nitrous acid, and then adding spirit of salt, or a solution of sea-salt, when a precipitation instantly ensues; the marine acid expels the nitrous, and, uniting with the silver, falls to the bottom in form of a white powder. The same precipitation would take place, if a solution of silver was made in the vitriolic acid.

Luna cornea weighs one-fourth more than the silver employed; yet, when perfectly washed, it is quite insipid to the taste. It does not dissolve in water, spirit of wine, aquafortis, or aqua-regis; but is in some small degree acted upon by the vitriolic acid. It melts in the fire as soon as it grows red-hot; and, on cooling, forms a ponderous brownish mass, which being cast into thin plates, becomes semitransparent, and somewhat flexible, like horn; whence its name *luna cornea*. A stronger fire does not expel the acid from the metal, the whole concrete either subliming entire, or passing through the crucible. It totally dissolves in volatile alkaline spirits without any separation of the metal. Exposed to the fire in a close copper vessel, it penetrates the copper, and tinges it throughout of a silver colour. Kunckel observes, that when carefully prepared, melted in a glass vessel, and suffered to cool slowly, to prevent its cracking, it proves clear and transparent; and may be turned into a lathe and formed into elegant figures. He supposes this to be the preparation which gave rise to the notion of malleable glass.

VII. *With Copper.* In the marine acid, copper dissolves but slowly. The solution, if made without heat, appears at first brown; but, on standing for some time, deposits a white sediment, and becomes green. On adding fresh copper, it becomes brown again, and now recovers its greenness more slowly than before. The white sediment, on being barely melted, proves pure and perfect copper of the same colour as at first. Copper calcined by fire communicates a reddish colour to this acid.

VIII. *With Iron.* The marine acid acts upon iron less

less vehemently than the nitrous, and does not dissolve so much; nevertheless, it attacks the metal briskly, so as to raise considerable heat and effervescence, and dissolve it into a yellow liquor. During the solution, an inflammable vapour arises as in the solution of this metal by vitriolic acid. This solution of iron does not crystallize. If it is evaporated, it leaves a greenish saline mass, which is soluble in spirit of wine, and runs in the air into an astringent yellow liquor. On distillation, some of the acid separates, and towards the end of the operation the spirit becomes yellow. This is followed by a yellowish, or deep reddish sublimate, which glistens like the scales of fishes; leaving behind a substance which consists of thin, glossy plates, like talc.

The solution of iron in spirit of salt, with the addition of some spirit of wine, is used in medicine as a corroborant, under the name of *tinctura martis*. The sublimate of iron is also used for the same purpose, and called *ens veneris*, or *flores martiales*. It is commonly directed to be prepared by subliming iron filings and sal ammoniac together. In the process, the sal ammoniac is partly decomposed, and a caustic alkaline liquor distils. Then the undecomposed sal ammoniac, and the martial sublimate above mentioned, arise together. The sublimate has a deeper or lighter yellow colour, according as it contains more or less iron. The name *ens veneris* is improper. It was given by Mr Boyle, who discovered this medicine. He imagined it to be a preparation of copper, having made use of a colcothar of vitriol containing both iron and copper. A medicine of this kind was lately sold with great reputation on the Continent, under the name of *Bestuchef's nervous tincture*. It was introduced by M. Bestuchef Field Marshal in the Russian service; but not long after it came into vogue in Prussia and other northern kingdoms of Europe: it made its appearance also in France, under the name of *General de la Motte's golden drops*. This happened through the infidelity of Bestuchef's operator, who, for a sum of money, violated the oath of secrecy he had taken to Bestuchef, and discovered the secret to de la Motte. To the latter it proved a very valuable acquisition; for he not only procured a patent for it from the king of France in 1730, with the exclusive privilege of selling it, but had a handsome pension settled upon him; selling his medicine besides a half a Louis d'or per phial.

The attention of the public was particularly drawn to these drops, by their remarkable property of losing their yellow colour in the sun, and regaining it in the shade, which induced many to believe that they contained gold; and in which opinion they were encouraged by de la Motte. Even chemists of no little reputation were deceived by this appearance; and M. Beaumé, imagining he had discovered the secret, published a preparation to the world as the true arcanum of la Motte's drops. It consisted of a calx of gold precipitated from aqua-regia by means of fixed alkali, and redissolved in nitrous acid, to which was added a large quantity of spirit of wine. Others, however, who could find nothing but iron by an analysis of the drops, refused their assent; and at length, in 1780, M. Beaumé's mistake was made evident by the publication of the process at the desire of the empress of Russia, who gave 3000 rubles for the receipt. The original *recipe* is perplexed, tedious, and expensive;
VOL. IV. Part II.

but when deprived of its superfluous parts, is nearly as follows. Six pounds of common pyrites and twelve of corrosive sublimate are to be triturated together, and then sublimed six or eight times till all the mercury is expelled. The residuum is to be boiled three times with thrice its quantity of water, and as often filtered, and lastly, distilled to dryness. By increasing the fire, a martial salt is at last sublimed into the neck of the retort; to three drachms of which are to be added 12 ounces of highly rectified spirit of wine, and the whole exposed to the rays of the sun. This is the yellow tincture; but there was also a white one, which, however, seems to be but of little value. It is made by pouring on the residuum of the last sublimation twelve pounds of highly rectified spirit of wine, and drawing it off by a gentle distillation after a few days digestion.—Mr Klaproth imagines, from the following experiment, that Bestuchef's tincture absorbs phlogiston from the rays of the sun. He poured a few drops of a solution of tartar into two ounces of distilled water, and divided this into two parts. Into one glass having poured a few drops of the tincture that had not been exposed to the sun, the iron was precipitated in the usual form of a yellow ochre; but on treating in the same manner a portion of the tincture that had been exposed to the solar rays, the precipitate fell of a bluish green colour.

IX. *With Tin*. Though the concentrated marine acid has a greater attraction for tin than any other acid, it does not readily dissolve this metal while the acid is in its liquid state; but may be made to dissolve it perfectly by the addition of a small quantity of spirit of nitre. Neumann observes, that an ounce of spirit of salt, with only a scruple of spirit of nitre, dissolved tin perfectly: but on inverting the proportions, and taking a scruple of marine acid to an ounce of the nitrous, four scruples, or four and an half, of tin, were dissolved into a thick pap; some more of the marine acid being gradually added, the whole was dissolved into a clear liquor. In making these solutions, a small quantity of black matter usually subsides.

The solution of tin is sometimes colourless; sometimes of a bluish, or yellow colour, according to different circumstances of the process. It is of the greatest consequence in dyeing, by not only heightening the colours, but making them more durable (See DYEING). It shoots into small crystals; and, if inspissated, deliquesces in the air.

Marine acid in its concentrated state volatilizes tin, and forms with it a thick liquor, which, from its inventor, is called *smoking liquor of Libavius*. To prepare this smoking liquor, an amalgam must be made of four parts of tin and five of mercury. This amalgam is to be mixed with an equal weight of corrosive mercury, by triturating the whole together in a glass mortar. The mixture is then to be put into a glass retort, and the distillation performed with a fire gradually increased. A very smoking liquor passes into the receiver; and towards the end of the distillation, a thick, and even concrete matter. When the operation is finished, the liquor is to be poured quickly into a crystal glass-bottle, with a glass stopper. When this bottle is opened, a white, copious, thick, and poignant fume issues, which remains long in the air without disappearing.

The acid in this liquor is far from being saturated,

nations.

and is capable of still dissolving much tin in the ordinary way. From this imperfect saturation, together with its concentration, proceeds partly its property of smoking so considerably: nevertheless, some other cause probably concurs to give it this property; for though it smokes infinitely more than the most concentrated spirit of salt, its vapours are, notwithstanding, much less elastic. It has all the other properties of concentrated marine acid when imperfectly saturated with tin. If it is diluted with much water, most of the metal separates in light white flocks. In dyeing, it produces the same effects as solution of tin made in the common way. If the distillation is continued after the smoking liquor of Libavius has come over, the mercury of the corrosive sublimate will then arise in its proper form.

811
Lead.

X. *With Lead.* Marine acid, whether in its concentrated or diluted state, has little effect upon lead, unless assisted by heat. If spirit of salt is poured on filings of lead, and the heat is increased so as to make the liquor boil and distil, a part of the acid will be retained by the metal, which will be corroded into a saline mass; and this, by a repetition of the process, may be dissolved into a limpid liquor. If lead is dissolved in aquafortis, and spirit of sea-salt, or sea-salt itself, added, a precipitation of the metal ensues; but if some aqua-regia is added, the precipitate is redissolved.

812
Plumbum
corneum.

The combination of lead with marine acid, has, when melted, some degree of transparency and flexibility like horn; whence, and from its resemblance to luna cornea, it is called *plumbum corneum*. This substance is used in preparing phosphorus, according to Mr Margraaf's method.

813
Quickfil-
ver.

XI. *With Quicksilver.* Marine acid in its limpid state, whether concentrated or diluted, has no effect upon quicksilver, even when assisted by a boiling heat; but if mercury is dissolved in the vitriolic or nitrous acids, and sea-salt, or its spirit, is added to the solution, it immediately precipitates the quicksilver in the same manner as it does silver or lead. If concentrated marine acid, in the form of vapour, and strongly heated, meets with mercury in the same state, a very intimate union takes place; and the produce is a most violent corrosive and poisonous salt, called *corrosive sublimate mercury*. This salt is soluble, though sparingly, in water; but is far from being perfectly saturated with mercury; for it will readily unite with almost its own weight of fresh quicksilver, and sublime with it into a solid white mass (which, when levigated, assumes a yellowish colour) called *mercurius dulcis*, *aquila alba*, or *calomel*.

814
Corrosive
sublimate.

815
Different
methods of
making.

There have been many different ways of preparing corrosive mercury, recommended by different chemists. Neumann mentions no fewer than ten. 1. From mercury, common salt, nitre, and vitriol. 2. From mercury, common salt, and vitriol. 3. Mercury, common salt, and spirit of nitre. 4. Solution of mercury in aquafortis and salt. 5. Solution of mercury in aquafortis, and spirit of salt, or the white precipitate. 6. Mercury, common salt, nitre, and oil of vitriol. 7. Edulcorated turbith mineral, and common salt. 8. Red precipitate, common salt, and oil of vitriol. 9. Edulcorated turbith mineral, and spirit of salt. 10. Mercury, sal ammoniac, and oil of vitriol.

From a view of these different methods, it is evident, that the intention of them all is to combine the

marine acid with quicksilver; and as this combination can be effected without making use of the nitrous acid, the greatest chemists have imagined that this acid, which is by far the most expensive of the three, might be thrown out of the process altogether, and the sublimate be more conveniently made by directly combining marine acid and mercury in a process similar to the distillation of spirit of salt. This method was formerly recommended by Kunckel; then published in the memoirs of the Academy of Sciences for 1730; and has been adopted and recommended by Dr Lewis.

The process consists in dissolving mercury in the vitriolic acid, as directed for making turbith mineral. The white mass remaining on the exsiccation of this solution is to be triturated with an equal weight of dried salt, and the mixture is then to be sublimed in a sand-heat; gradually increasing the fire till nothing more arises.

Neumann observes, that there is a considerable difference in the quality of sublimate made by the different methods he mentions; particularly in those made with or without nitre. This we have also found to be the case; and that sublimate made without the nitrous acid is never so corrosive, or soluble in water, as that which is made with it: nor will it afterwards take up so large a quantity of crude mercury as it otherwise would, when it is to be formed into calomel. The above process, therefore, tho' very convenient and easy, is to be rejected; and some other in which the nitrous acid is used, substituted in its stead. The reason of these differences is, that the spirit of salt must by some means or other be dephlogisticated before it can unite in sufficient quantity with the metal, into the compound desired, which is accomplished by the addition of nitrous acid.

From Tachenius, Neumann gives us the following process, which he says was the method of making sublimate at London, Venice, and Amsterdam. Two hundred and eighty pounds of quicksilver, 400 pounds of calcined vitriol, 200 pounds of nitre, the same quantity of common salt, and 50 pounds of the caput mortuum remaining after a former sublimation, or (in want of it) of the caput mortuum of aquafortis, making, in all, 1130 pounds, are well ground, and mixed together; then set to sublime in proper glasses placed in warm ashes, the fire is increased by degrees, and continued for five days and nights. In the making such large quantities, he says, some precautions are necessary, and which those constantly employed herein are best acquainted with. The principal are, the due mixture of the ingredients, which in some places is performed in the same manner as that of the ingredients for gun-powder: that a head and receiver be adapted to the subliming glass, to save some spirit of nitre which will come over. (Here a bent tube of glass will answer the purpose, as already mentioned). The fire must not be raised too hastily. When the sublimate begins to form, the ashes must be removed a little from the sides of the glass, or the glass cautiously raised up a little from the ashes. (This last, we think, is highly imprudent.) Lastly, the laboratory must have a good chimney, capable of carrying off the noxious fumes. The above-mentioned quantities commonly yield 360 pounds of sublimate; the 280 pounds of quicksilver gaining 80 from the 200 pounds of sea-salt. The makers of sub-
limate

816

nations.

limate in France, he says, employ, in one operation, only 20 pounds of mercury. This they dissolve in aquafortis, evaporate the solution to dryness, mix the dry matter with 20 pounds of decrepitated sea-salt and 60 of calcined vitriol, and then proceed to sublimation.

817
Observa-
tions on the
different
methods.

The above processes, particularly the last, are unexceptionable as to the production of a sublimate perfectly corrosive; but the operation, it is evident, must be attended with considerable difficulty, by reason of the large quantity of matter put into the glass at once. We must remember, that always on mixing a volatile salt with a quantity of fixed matter, the sublimation of it becomes more difficult than it would have been had no such matter been mixed with it. It is of considerable consequence, therefore, in all sublimations, to make the quantity of matter put into the glass as little as possible. It would seem more proper, instead of the calcined vitriol used in the processes last mentioned, to dissolve the mercury in the vitriolic acid, as directed for turbith mineral, and sublime the dry mass mixed with nitre and sea-salt.

818
Supposed a-
dulteration
with arse-
nic.

It has been said, that corrosive sublimate mercury was frequently adulterated with arsenic; and means have even been pointed out for detecting this supposed adulteration. These means are, to dissolve a little of the suspected salt in water, and add an alkaline lixivium to precipitate the mercury. If the precipitate was of a black colour, it was said to be a certain sign of arsenic. This, however, shows nothing at all, but that either the alkali contains some inflammable matter, which, joining with the precipitate, makes it appear black; or that the sublimate is not perfectly corrosive; for if a volatile alkali is poured on levigated *mercurius dulcis*, the place it touches is instantly turned black.

819
Mercurius
dulcis.

Mercurius dulcis, or calomel, is prepared by mixing equal parts, or at least three of quicksilver with four of sublimate; after being thoroughly ground together in a glass or stone mortar, they are to be poured through a long funnel into a bolt-head, and then sublimed. The medicine has been thought to be improved by repeated sublimations, but this is found to be a mistake. Mr Beaumé has found that *mercurius dulcis* cannot be united with corrosive sublimate in the way of sublimation; the former, by reason of its superior volatility, always rises to the top of the vessel.

820
Zinc vola-
tilized.

XII. *With Zinc*. This semimetal dissolves readily in the marine acid into a transparent colourless liquor. It is volatilized, as well as most other metallic substances, by this combination, as appears from the following process delivered by Neumann.

"Equal parts of filings of zinc and powdered sal ammoniac being mixed together, and urged with a gradual fire in a retort; at first arose, in a very gentle heat, an excessively penetrating volatile spirit, so strong as to strike a man down who should inadvertently receive its vapour freely into the nose. This came over in subtile vapours, and was followed by a spirit of salt in dense white fumes. In an open fire, white flowers succeeded; and at length a reddish and a black butter. In the bottom of the retort was found a portion of the

zinc in its metalline form, with a little ponderous and fixed butyraceous matter, which liquefied in the air. The lump was far more brittle than zinc ordinarily is; of a reddish colour on the outside, and blackish within. The bottom of the retort was variegated with yellow and red colours, and looked extremely beautiful. The remaining zinc was mixed afresh with equal its weight of sal ammoniac, and the process repeated. A volatile alkaline spirit and marine acid were obtained as at first; and in the retort was found only a little black matter. When the zinc was taken at first in twice the quantity of the sal ammoniac, the part that preserved its metallic form proved less brittle than in the foregoing experiment, and the retort appeared variegated in the same manner. On endeavouring to rectify the butter, the retort parted in two by the time that one half had distilled." The nature of this combination is unknown.

XIII. *With Regulus of Antimony*. This semimetal cannot be united with the marine acid unless the latter is in its most concentrated state. The produce is an excessively caustic thick liquid, called *butter of antimony*. The process for obtaining this butter is similar to that for distilling the smoking spirit of Libavus. Either crude antimony, or its regulus, may be used: for the spirit of salt will attack the reguline part of this mineral without touching the sulphureous. Three parts of corrosive sublimate are to be mixed with one of crude antimony; the mixture to be digested in a retort set in a sand heat; the marine acid in the sublimate will unite with the reguline part of the antimony. Upon increasing the fire, the regulus arises, dissolved in the concentrated acid, not into a liquid form, but that of a thick unctuous substance like butter, from whence it takes its name. This substance liquefies by heat, and requires the cautious application of a live coal to melt it down from the neck of the retort. By rectification, or exposure to the air, it becomes fluid like oil, but still retains the name of butter. If water is added to butter of antimony, either when in a butyraceous form, or when become fluid by rectification, the antimony is precipitated in a white power called *powder of algaroth*, and improperly *mercurius vite*. This powder is a violent and very unsafe emetic. The butter itself was formerly used as a caustic; but it was totally neglected in the present practice, until lately that it has been recommended as the most proper material for preparing emetic tartar. (See below.) Mr Dolfus recommends the following method as the best for making butter of antimony; viz. two ounces and a quarter of the grey calx of antimony, eight ounces of common salt, and six of acid of vitriol. By distilling this mixture, ten ounces of the antimonial caustic were obtained; and in order to determine the quantity of metal contained in it, he mixed two ounces of the caustic with four ounces of water; but thus such a strong coagulum was formed, that he was not able to pour off any of the water even after standing 24 hours. The precipitate, when carefully dried, weighed 50 grains. The result was much the same when glass of antimony was used, only that the precipitate was much more considerable; half an ounce of the caustic then yielding 60 grains, though at another time only 50 grains were obtained. In the re-

Butter of
antimony.

Marine
Acid and
its Combi-
nations.

residuum of the former experiment he found 30 grains of an earthy substance, chiefly a combination of calcareous earth with muriatic acid.

When the mercurius vitæ precipitates, the union between the marine acid and regulus is totally dissolved; so that the powder, by frequent washings, becomes perfectly free from every particle of acid, which unites with the water made use of, and is then called, very improperly, *philosophic spirit of vitriol*.

822
Sympathe-
tic ink.

XIV. *With Regulus of Cobalt*. Pure spirit of salt dissolves this semimetal into a reddish yellow liquor, which immediately becomes green from a very gentle warmth. On saturating the solution with urinous spirits, the precipitate appears at first white, but afterwards becomes blue, and at length yellow. If the nitrous acid is added to solutions of regulus of cobalt, they assume a deep emerald green when moderately heated, and on cooling become red as at first. Duly evaporated, they yield rose-coloured crystals, which change their colour by heat in the same manner. This solution makes a curious sympathetic ink, the invention of which is commonly ascribed to M. Hellot, though he himself acknowledges that he received the first hint of it from a German chemist in 1736. Any thing wrote with this solution is invisible when dry and cold; but assumes a fine green colour when warm, and will again disappear on being cooled; but if the heat has been too violent, the writing still appears. M. Hellot observes, that if nitre or borax be added to the nitrous solution, the characters wrote with it become rose-coloured when heated; and if sea-salt is afterwards passed over them, they become blue; that with alkali sufficient to saturate the acid, they change purple and red with heat.—A blue sympathetic ink may be made from cobalt in the following manner. Take of an earthy ore of cobalt, as free from iron as possible, one ounce. Bruise it, but not to too fine a powder. Then put it into a cylindrical glass, with 16 ounces of distilled vinegar, and set the mixture in hot sand for the space of six days, stirring it frequently; or else boil it directly till there remain but four ounces. Filter and evaporate it to one half. If your solution be of a rose colour, you may be certain that your cobalt is of the right sort. A red brown colour is a sign of the solution containing iron; in which case the process fails. To two ounces of the solution thus reduced, add two drachms of common salt.—Set the whole in a warm place to dissolve, and the ink is made.

823
Oil of arse-
nic.

XV. *With Regulus of Arsenic*. This substance is soluble in all acids; but the nature of the compounds formed by such an union is little known. If half a pound of regulus is distilled with one pound of corrosive sublimate, a thin smoking liquor and a butyraceous substance will be obtained, as in making the smoking liquor of Libavius. By repeated rectifications, this butter may be almost all converted into spirit. If equal parts of the arsenic and sublimate are used, a ponderous black oil comes over along with the spirit, which cannot be mixed with it. By rectification in a clean retort, they will become clear, but still will not incorporate. If they are now returned upon the red mass remaining in the first retort, and again distilled, a much more ponderous oil than the former will be obtained.

824
Marine
ether.

XVI. *With Inflammable Substances*. The acid of sea-

salt is very little disposed to contract any union with the phlogiston, while in a liquid state; and much less so, even in its most concentrated state, than either the vitriolic or nitrous. Mr Beaumé, however, has found, that a small quantity of ether, similar to that prepared with the vitriolic and nitrous acids, may be obtained by causing the fumes of the marine acid unite with those of spirit of wine. Others, and particularly some German chemists, attempted to make this liquor, by employing a marine acid previously combined with metallic substances, such as butter of antimony. The smoking liquor of Libavius succeeds best. If equal parts of this liquor and highly rectified spirit of wine are distilled together, a considerable quantity of true ether is produced; but which, like the vitriolic and nitrous ether, must be rectified in order to its greater purity. The tin contained in the smoking liquor is separated and precipitated in white powder. In this process, the acid is probably more disposed to unite with the spirit of wine, by having already begun to combine with the inflammable principle of the metal.—For marine ether, Mr Dollfus recommends to put into a retort four ounces of digestive salt previously well dried and powdered, and two ounces of manganese; pouring upon this a mixture of five ounces of spirit of wine and two of oil of vitriol; the first five ounces and a half of the distilled liquor being poured back on the residuum, and the whole afterwards drawn off by a gentle heat. The spirit of salt thus obtained had a very penetrating agreeable odour, somewhat like that of nitrous ether; and at first swam upon the top of water, but at length mixed with it on being agitated for a long time. Towards the end of the distillation a little oil was obtained, which did not mix with the water; and by the addition of four ounces more of spirit of wine, more of the dulcified acid was obtained. With regard to this kind of ether, however, Mr Westrumb denies that it can be made by any method hitherto known; and insists, that all the liquids as yet produced under the name of marine ether are in reality dulcified spirit of salt, and not true ether, which will swim on the top of water.

Dr Priestley has observed, that the pure marine acid, when reduced to an invisible aerial state, has a strong affinity with phlogiston; so that it decomposes many substances that contain it, and forms with them an air permanently inflammable. By giving it more time, it will extract phlogiston from dry wood, crusts of bread not burnt, dry flesh; and, what is still more extraordinary, from flints. From what has been above related, it appears that the dephlogisticated spirit of salt has a very strong attraction for phlogiston.

Essential oil of mint absorbed the marine acid air pretty fast, and presently became of a deep brown colour. When taken out of this air, it was of the consistence of treacle, and sunk in water, smelling differently from what it did before; but still the smell of the mint was predominant. Oil of turpentine was also much thickened; and became of a deep brown colour, by being saturated with acid air. Ether absorbed the air very fast; and became first of a turbid white, and then of a yellow and brown colour. In one night a considerable quantity of strongly inflammable air was produced.

Having once saturated a quantity of ether with acid air,

825
Attraction

sten.

Marine
Acid and
its Combi-
nations.

air, he admitted bubbles of common air to it, through the quicksilver by which it was confined, and observed that white fumes were made in it, at the entrance of every bubble, for a considerable time. Having, at another time, saturated a small quantity of ether with this kind of air, and the phial which contained it happening to be overturned, the whole room was instantly filled with a white cloud, which had very much the smell of ether, but peculiarly offensive. Opening the door and window of the room, this light cloud filled a long passage and another room. The ether, in the mean time, was seemingly all vanished: but, sometime after, the surface of the quicksilver in which the experiment had been made was covered with a very acid liquor, arising probably from the moisture in the atmosphere, attracted by the acid vapour with which the ether had been impregnated. This seems to show, that, however much disposed the marine acid may be to unite with phlogistic matters when in its aerial state, the attraction it has for them is but very slight, and still inferior to what it has for water.

Camphor was presently reduced into a fluid state by imbibing this acid air; but there seemed to be something of a whitish sediment in it. After continuing two days in this situation, water was admitted to it, upon which the camphor immediately resumed its former solid state; and to appearance was the same substance that it had been before.

Strong concentrated oil of vitriol, being put to marine acid air, was not at all affected by it in a day and a night. In order to try whether it would not have more power in a condensed state, it was compressed with an additional atmosphere; but, on taking off this, the air expanded again, and was not in the least diminished. A quantity of strong spirit of nitre was also put to it without any sensible effect. From these last experiments it appears, that the marine acid is not able to dislodge the other acids from their union with water.

Besides the acids already mentioned, Mr Homberg describes an artificial one generated by mixing two ounces and a half of luna cornea, with an ounce and a half of tin calcined alone and without addition, by means of fire. The mixture is to be exposed to a naked fire in a coated retort, of which two thirds ought to be left empty; when a brownish matter, an ounce and a half in weight, will adhere to the neck of the retort. This matter is tin combined with the marine acid, and the residuum is silver deprived of the same acid, which may therefore now be melted together without any loss. The sublimate, well powdered and dried, is to be equally divided into two phials, and sublimed; by repeating which operation two or three times, a volatile salt, of an acid nature, very white and transparent, is obtained. The residuum of these sublimations is always calx of tin.

§ 4. Of the Fluor Acid.

826
First discovered by
Mr Mar-
graaf
827
How prepared.

THIS acid was discovered some time ago by Mr Mar-
graaf, and more fully investigated by Mr Scheele. The experiments by which it was originally produced, and its properties ascertained, are as follows:

I. Two ounces of concentrated vitriolic acid were poured upon an equal quantity of fluor, which had been

previously pounded in a glass mortar, and then put in to a retort, to which a receiver was adapted, and the juncture closed with grey blotting-paper. On the application of heat, the mass began to effervesce and swell, invisible vapours penetrated every where through the joining of the vessels, and towards the end of the process white vapours arose, which covered all the internal parts of the receiver with a white powder.—The mass remaining in the retort was as hard as a stone, and could not be taken out without breaking the vessel. The lute was quite corroded and friable.

II. The process was repeated exactly in the same manner, excepting only that a quantity of distilled water was put into the receiver. A white spot soon began to form on the surface of the water, just in the centre, and immediately under the mouth of the retort. This spot continually increased, till at last it covered the whole surface of the water, forming a pretty thick crust, which prevented the communication of the water with new vapours that came over. On gently agitating the receiver, the crust broke, and fell to the bottom; soon after which a new crust like the former was produced. At last the receiver, and soon after the retort also, became white in the inside. The vessels, when cooled, were found much corroded internally. In the receiver was an acid liquor mixed with much white matter, separable by filtration.

III. This white matter when edulcorated and dried, showed itself to be siliceous earth, by the following properties. 1. It was rare, friable, and white. 2. It was not sensibly soluble in acids. 3. It did not make a tough paste with water, but was loose and incoherent after being dried. 4. It dissolved by boiling in lixivium tartari, and the solution in cooling assumed a gelatinous consistence. 5. In its pure state it suffered no change in the strongest heat; but when mixed with alkali, it boiled, frothed up, and formed a glass in a melting heat. 6. It dissolved in borax without swelling.

IV. To determine whether this earth was formed during the process, he poured vitriolic acid upon powdered fluor contained in a cylinder of brass which was closed exactly with a cover, after having suspended over the mixture an iron nail and a bit of charcoal. On opening the vessel two hours afterwards, he found the nail and charcoal unchanged; but on moistening them, he found both covered with a white powder in a short time. This powder had all the properties of siliceous earth; and as in the experiment he had made no use of glass vessels, he concluded that it did not proceed from the glass vessels, as might have been suspected from their being so much corroded, but was generated in some other way.

V. Having recomposed fluor by saturating the acid with calcareous earth, he treated the compound in the same manner as the natural fluor, with a similar result; and repeating the experiment five times over, he constantly found the siliceous earth and acid diminish considerably, so that at last scarce any mark of acidity was left. Thence he concluded, that all the fluor acid united itself by degrees with the vapours of the water, and thus formed the siliceous earth. "It may be objected (says Mr Scheele), that the fluor acid is perhaps already united by nature with a fine siliceous powder,

Fluor acid
proved to
be different
from that
of sea-salt,

der, which it volatilizes, and carries over in distillation, but leaves it as soon as it finds water to unite with, just as muriatic acid parts with the regulus of antimony, when butter of antimony is dropped into water. But if this was the case, the fluor acid would leave the whole quantity of siliceous earth thus combined with it in the first distillation, and therefore show no mark of its presence in the following processes. When I put spirit of wine into the receiver instead of water, no siliceous earth was produced; but the alcohol became sour. When I put an unctuous oil into the receiver, all the fluor acid penetrated through the crevices of the lute, and neither united with the oil, nor produced a siliceous earth. This happened also when acid of vitriol was put into the receiver. If therefore the siliceous earth was not a product of each distillation, but, being previously contained in the acid, was only deposited from it in consequence of the union of the acid with a third substance, I think the siliceous earth ought equally to appear when alcohol was put into the receiver, with which it unites, as well as with water; but as this does not happen, I conclude that not all the siliceous earth which is deposited upon the surface of water during the distillation of the fluor acid, was previously dissolved in this acid."

This opinion of Mr Scheele did not meet with general approbation. M. Boullanger endeavoured to show, that the fluor acid is no other than the muriatic intimately combined with some earthy substance; and Mr Monnet maintained that it is the same with that of vitriol volatilized by some extraordinary connection with the fluor; which opinion was also maintained by Dr Priestley. Mr Scheele contested these opinions, but found much greater difficulty in supporting his own opinions than in overthrowing those of his adversaries. Boullanger insisted that fluor acid precipitates the solutions of silver and quicksilver, producing luna cornea with the former, and mercurius dulcis with the latter. Mr Scheele owns that fluor acid precipitates both these metals, but the precipitate obtained is in very small quantity, and the little that is produced arises only from a small quantity of sea-salt with which the fluor, as well as all other calcareous substances, is generally mixed. The greatest part of the acid, therefore, will not precipitate the solutions of these metals, which it ought to do upon Mr Boullanger's hypothesis. Mr Scheele then proceeds to show a method of separating this small quantity of marine acid from that of fluor. A solution of silver made with nitrous acid is to be precipitated with alkali of tartar, and as much acid of fluor poured upon theedulcorated powder as is sufficient to give an excess of acid; after which the solution is to be filtered. This solution of silver in fluor acid is then to be dropped into that acid we desire to purify, till no more precipitation ensues; after which the acid is filtered through grey paper, and distilled to dryness in a glass retort. The aqueous part comes over first, but is soon followed by fluor acid, which covers the inside of both the vessels, together with the surface of the water in the receiver, with a thick siliceous crust. The acid, thus rectified, does not precipitate solution of silver in the least, nor otherwise show the smallest sign of muriatic acid.

That the fluor acid is different from that of vitriol,

Mr Scheele proved by the following experiment. Upon one ounce of pure levigated fluor with alcohol, he poured three ounces of concentrated oil of vitriol, and distilled the mixture in a sand-bath, having previously put 12 ounces of distilled water into the receiver. He then took other three ounces of the same acid diluted with 24 ounces of water, to which he afterwards added lixivium tartari previously weighed, till he attained the exact point of saturation. After the distillation he weighed the remaining lixivium; having kept up such a degree of heat for eight hours as was not sufficient to raise the vitriolic acid. On breaking the retort, and reducing the mass to powder, he boiled it in a glass vessel with 24 ounces of water for some minutes; after which he added just as much lixivium tartari as he had found before to be requisite for the saturation of three ounces of the vitriolic acid, and continued the boiling for a few minutes longer. On examining the solution, it was found to contain a vitriolated tartar perfectly neutralized, neither acid nor alkali prevailing in any degree; which showed that no vitriolic acid had passed into the receiver. The saline matter being then extracted with hot water, the remaining earth was found to weigh $9\frac{1}{2}$ drachms. Two drachms of this dissolved in muriatic acid, excepting only a small quantity of matter which seemed to be fluor undecomposed, and which on being dried weighed only nine grains. Into one part of this solution he poured some acid of sugar, and into another vitriolic acid. The former produced saccharated lime, and the latter gypsum. A third part was evaporated to dryness, and left a deliquescent salt; and the remaining part of the earth burned in a crucible, produced a real quicklime.

Thus it appeared that the real basis of fluor is quicklime, and likewise that the fluor acid is different from that of vitriol, as appears further from the following considerations: 1. Pure fluor acid does not precipitate terra ponderosa, nor solution of lead in nitrous acid. 2. The same acid, when saturated with alkali of tartar, evaporated to dryness, and afterwards melted with powdered charcoal, does not produce any hepar sulphuris.

Mr Monnet, in order to support his hypothesis, denies that fluor contains any calcareous earth. In proof of which he adduces the following experiment: Equal quantities of alkali and fluor were melted together, with little or no change on the mineral; for, after having taken away by lixiviation the alkali employed, he dissolved the fluor remaining on the filter in nitrous acid, adding vitriolic acid to the solution; and because he obtained no precipitate, concluded at once, that fluor contains no calcareous earth. Mr Scheele, on the contrary, affirms that all solutions of fluor yield a precipitate of gypsum whenever vitriolic acid is added to them. He explains Mr Monnet's failure, by supposing that he had diluted his solution with too great a quantity of water.

Mr Wiegleb, dissatisfied with the hypothesis of Scheele, as well as others, concerning the fluor acid, began a new set of experiments on the mineral. Having first accurately repeated those made by Mr Scheele, he proceeded to inquire into the origin of the siliceous earth, in the following manner: Having first weighed the retort destined for the experiment in

ceous earth.

an

Fluor Acid and its Combinations. an accurate manner, and found that its weight was two ounces and five drachms, he put into it two ounces of calcined fluor in powder, adding, by means of a glass tube, $2\frac{1}{2}$ ounces of oil of vitriol. The retort was then placed on the furnace; and a receiver, which when empty weighed two ounces, two drachms, and 30 grains, and now contained two ounces of distilled water, was luted to it. The distillation was conducted with all possible care, and at last pushed till the retort grew red hot; but it was found impossible to prevent a few vapours from penetrating through the lute. Next day the retort, separated from the receiver, was found to weigh, together with its contents, five ounces, five drachms, and 30 grains; and consequently had lost in weight one ounce, three drachms, and 30 grains. The receiver, which, with the water, had originally weighed four ounces, two drachms, and 30 grains, now weighed five ounces and three drachms, and had therefore gained one ounce and 30 grains. This gain, compared with the loss of the retort, shows that the retort lost more by three drachms than the receiver gained; so that these must have undoubtedly passed through the luting in form of vapour.

To determine the point in question, the empty vessels, with what had been put into them, were accurately weighed; when the weights and loss upon the whole were found to be as follows:

	oz.	dr.	gr.
The empty retort	2	5	0
Calcined fluor	2	0	0
Oil of vitriol	2	4	0
Total weight before distillation	7	1	0
After it	5	5	30
Loss of retort	1	3	30
The empty receiver weighed	2	2	30
The water put into it	2	0	0
Total weight before distillation	4	2	30
Total weight after distillation	5	3	0
Gain of receiver	1	0	30

Deducting this gain of weight in the receiver from the loss of weight in the retort, we find, that three drachms were wanting on the whole, which must undoubtedly, as already observed, have been dissipated in vapour. The retort being now broken, and the dry earth both in its neck and arch separated as accurately as possible, it was found to weigh three drachms; the residuum in the retort weighed three ounces, two drachms, and 40 grains. Now, as the mass in the retort had originally weighed four ounces and four drachms, it appeared, by deducting the residuum, to have suffered, on the whole, a loss of one ounce, one drachm, and 20 grains. To determine the loss more accurately, the following calculations were made:

	oz.	dr.	gr.
The white earth separated from the neck and arch of the retort	0	3	0
Gain of the receiver	1	0	30
Lost in vapour	0	3	0
Total	1	6	30

Here Mr Wiegleb was surprised to find, that the

Fluor Acid and its Combinations. matter which came from the retort amounted to more by five drachms ten grains than the mass in the retort had lost of its original weight; to illustrate which it was necessary to weigh the retort and receiver by themselves. The pieces of the retort now weighed only one ounce seven drachms and 50 grains; whereas, before the process, the weight of the retort was two ounces five drachms. It appeared, therefore, that it had lost five drachms ten grains, the very quantity which had been gained by the receiver. This last had lost nothing of its original weight.

The fluid in the receiver was next diluted with four ounces of distilled water, and the whole poured out on a filter, in order to separate the earthy matter with which it was mixed, and fresh water poured upon it to take out all the acid: after which the earth was dried, and found to weigh 57 grains. The clear liquor was then diluted with more distilled water, and afterwards precipitated with spirit of sal ammoniac prepared with fixed alkali. A brisk effervescence took place before any precipitate began to fall, but ceased soon after the precipitation took place. The whole mixture became gelatinous; and the precipitate, when dry, weighed two drachms. The whole quantity of earth, therefore, obtained in this process amounted to five drachms 47 grains, which is forty seven grains more than the retort had lost in weight. This excess is, by our author, attributed to part of the acid still adhering to it, and to the accession of some moisture from the air; to determine which he heated each of the parcels of earth red hot separately, and thus reduced them to four drachms 52 grains, which is less by 18 grains than the loss of the retort, and which, he is of opinion, must have escaped in the three drachms of vapour.

From this experiment Mr Wiegleb concludes, that the earth produced in the distillation of fluor proceeds neither from the spar nor from a combination of the acid with water, but from the solution of the glass by the sparry acid. To his opinion also Dr Crell accedes. "In distilling fluor (says he) with oil of vitriol, I have found the retort as well as the receiver very much corroded. I poured the acid obtained by the process into a phial furnished with a glass stopper, and observed after some time a considerable deposition. I then poured the liquor into another phial like the former; and that it might neither on the one hand attack the glass, nor on the other compose siliceous earth with the particles of water, according to Mr Scheele's hypothesis, I added highly rectified spirit of wine. I saw, however, after some time, another considerable deposition. This seemed also to proceed from the glass that had been before dissolved, which the acid let fall in consequence of the gradual combination with the spirit of wine; otherwise we must suppose, what to me appears incredible, that the acid decomposes the spirit, attracts the water, and forms the earth."

This singular acid has been still further examined by Mr Meyer. He informs us, that, among Mr Scheele's experiments, he was particularly struck by one in which no earthy crust was obtained, after putting spirit of wine into the receiver. Mr Meyer repeated this experiment, hoping, that when but little spirit was put into the receiver, he might be able to procure a new kind of ether. An ounce of finely powdered fluor, which had been previously heated red hot, was put into a glass

glass retort, to which was fitted a receiver contain-
ing three ounces of highly rectified French brandy.
The distillation was continued for three hours with
a gentle heat; when the acid, having made its way
through the bottom, put an end to the process. No
crust could be perceived on the surface of the spi-
rit; but in the place where it had been in con-
tact with the receiver there was a thin ring of transpa-
rent jelly. The same mixture of oil of vitriol and fluor
was therefore again put into a retort of very strong
glass, and the same spirit put into the receiver. The
distillation was conducted two hours with a gentle, and
afterwards with a stronger, heat. When it was half
over, the spirit began to change into a thin jelly; and
at the end of the process some firmer pieces were found
at the bottom. These were washed with spirit of
wine; and in order to obtain the spirit together with
the acid in a pure state, it was put into a large retort,
and again subjected to distillation. As the retort grew
warm, the opal-coloured spirit became clear and swell-
ed, what remained becoming again gelatinous; a good
deal of earth remained behind, but did not adhere firmly
to the retort, which was smooth in the inside, though full
of shallow excoriations. It was also evident, that the
glass was actually corroded, and that the earthy mat-
ter is not a mere crust adhering to the inside. The
jelly being thoroughlyedulcorated, as well as the earth
that remained in the retort after the rectification, and
that which was dissolved in the water precipitated by
spirit of sal ammoniac, the whole quantity amounted
to two drachms. That which had separated spontane-
ously was semitransparent. "As this earth (says he)
showed the properties of siliceous earth, and the glass,
which was so much corroded, consists in great measure
of it, the greatest part of it might come from the glass,
and the rest of it perhaps be a constituent part of the fluor
itself. In order to ascertain this, it was necessary to ob-
tain the fluor acid quite free from siliceous earth. I there-
fore exposed the ley, which I had procured by the pre-
cipitation of the earth with sal ammoniac, to a gentle
evaporation in a slightly covered glass vessel. The pro-
duct was one drachm 56 grains of an ammoniacal salt;
the glass did not appear to have been attacked. Half
a drachm of this salt was sublimed in a small retort,
which, towards the end of the operation, was laid on
the bare fire. No crust appeared on the surface of the
water in the receiver. At the bottom of the retort
lay a little flocculent earth of a light grey colour, above
which the internal surface was covered with a white
pellicle that reflected various colours; and in the neck
there was a sublimate. The thin pellicle easily sepa-
rated in many places from the glass, which was
smooth beneath, though not without some small fur-
rows. I poured water both upon the ammoniacal salt
and crust; in consequence of which it acquired a very
sour taste, and coloured the tincture of turnsole red.
The white crust that was left behind undissolved weigh-
ed five grains, and melted into a green glass without
addition. This was nothing but the glass that had
been corroded by the fluor acid; but as this acid can
be set loose only by strong heat, it had done no more
than corrode the glass, without passing over along with
it in the form of vapour, and then depositing it again
on the water. For, upon pouring two drachms of oil
of vitriol upon half a drachm of this ammoniacal salt,
N^o 73.

a little moistened, and placed in a glass retort, a great
foam arose, and the thick vapours that ascended cover-
ed the water in the receiver with a white crust. A scrup-
le of the salt on solution, left behind a grain of earth,
which, as I conjecture, it had taken up during the eva-
poration in the glass vessel."

To prevent this, our author distilled half an ounce
of fluor with an ounce of oil of vitriol for five hours.
The crusts were separated from the water; they weigh-
ed, after being well washed and dried, eleven grains;
they were white and very flocculent; thirty-two grains
of siliceous earth were precipitated from the filtered
water: the ley was then evaporated in a leaden vessel,
and yielded 80 grains of salt. As glass vessels were no
longer to be trusted, a piece of a gun-barrel furnished
with a cover, and terminated by a bent tube, intended to
serve instead of the neck of a retort, was afterwards
used; and with this apparatus the following experi-
ments were made:

1. Half a drachm of the newly prepared sal-ammo-
niac was distilled for two hours with two drachms of
oil of vitriol, into a glass receiver containing an ounce
of water. No vestige of a crust could be perceived on
the water, but some earth was perceived in the receiver,
where the vapours having ascended through the tube,
came into contact with the wet glass; and here the
surface was become sensibly rough. On the addition
of volatile alkali, a few flocculi of siliceous earth, a-
mounting only to one-fourth of a grain, were thrown
down out of the water.

2. A drachm of oil of vitriol was added to a drachm
and an half of the salt; but a leaden receiver was now
used, containing an ounce of water as before. The
water acquired an unpleasant smell, but showed no
signs of a crust. On the addition of spirit of sal am-
moniac, a little grey earth weighing half a grain fell to
the bottom.

3. A scruple of this salt, mixed with an equal quan-
tity of white sand in fine powder, and distilled with a
drachm and an half of oil of vitriol, into an ounce of
water in the leaden receiver, showed no sign of a crust.
The water had a putrid smell, and left on the filter
two grains and an half of grey earth, which ran under
the blow-pipe into a grain of lead. Volatile alkali
precipitated five grains of grey earth, which melted on
the addition of a little salt of tartar into a black glo-
bule, though the blow-pipe alone made no change
in it.

4. To 13 grains of the same ammoniacal salt a drachm
of oil of vitriol and two scruples of green glass, broken
into small pieces, were added. The iron tube had
scarce become warm, when a great crust of siliceous
earth was perceived on the surface of the water, and
the same appearance on the moist sides of the vessel.
It did not, however, seem to increase during the re-
mainder of the distillation. A grain and a quarter of
earthy matter remained on the filter, consisting partly
of white films, which ran under the blow-pipe into a
greenish glass.

5. To ascertain this matter still more clearly, a
different species of mineral fluor was used, which be-
ing distilled with a double quantity of oil of vitriol,
and with a drachm of water in the receiver, yielded a
thin pellicle of the appearance of lead, but no siliceous
crust. Volatile alkali threw down $2\frac{1}{4}$ grains of grey
earth.

Fluor Acid
and its
Combina-
tions.

earth.—A drachm mixed with the same quantity of pulverized sand afforded a pellicle of lead interspersed with a few particles of white crust, which ran into glass under the blow-pipe. Volatile alkali precipitated eight grains.—A drachm, mixed with an equal quantity of green glass reduced to powder, swelled a good deal, and yielded a thick siliceous crust.

6. To a drachm of green fluor that had been heated and powdered were added two drachms of oil of vitriol, still employing the iron tube. A piece of wet charcoal was also suspended in the inside, a cover fixed on the tube, and the latter was heated for about 15 minutes in a sand bath. Observing now that the charcoal was dry, and had no earth upon it, a scruple of sand in fine powder was added, the charcoal was wetted and replaced, but nothing appeared. Some bits of green glass were then thrown into the mixture, which instantly foamed up and ran over. The charcoal was not replaced in the tube, nor was it any longer necessary, as it gained a covering of white powder by being held a very few moments over the orifice.

846
An experi-
ment of Mr
Scheele's
explained.

Mr Scheele, in one of his experiments, observes, that he observed the white powder on a piece of charcoal that had been moistened and suspended over fluor to which vitriolic acid was added. As this experiment was made in metallic vessels, Mr Meyer conjectures, that the mortar used for reducing the fluor to powder was of soft glass, and that the phenomenon was occasioned by the abrasion of some particles of glass.

847
Of the
quantity of
siliceous
earth car-
ried along
with fluor
ac.d.

7. To determine whether the acid can carry up much more of the siliceous earth than is sufficient to saturate it, an ounce and an half of pure oil of vitriol was added in a retort of glass, and three ounces of water put into the receiver. The retort was corroded through in an hour's time, and the crust on the water weighed ten grains. The liquid being then filtered and divided into two equal parts, one was precipitated with caustic volatile, and the other with mild fixed vegetable, alkali. The former yielded 25 grains of siliceous earth, and the latter 68 grains of a precipitate, which flowed under the blow-pipe, ran into the pores of charcoal, and gave out strong vapours of fluor acid. The reason of this difference shall be explained when we come to treat of siliceous earth.

848
Violent ac-
tion of
fluor acid
upon glass.

8. To a mixture of half an ounce of fluor and the same quantity of glass, in powder, 12 drachms of oil of vitriol were put in a small retort, half filled with the mixture. The ingredients acted upon each other so violently that they rose up into the neck of the retort; and the operation being intermitted on account of the noxious vapour they emitted, the retort was found next day covered with fasciculated crystals like hoarfrost.—The experiment being repeated in a more capacious retort, and the mixture thoroughly blended by agitation, it became a thick mass, and swelled like dough in fermentation: the bottom of the retort grew very hot, and the siliceous crust appeared on three ounces of water in the receiver. The distillation being continued for three hours, 16 grains of siliceous earth were found on the surface, and the precipitate by volatile alkali weighed 56 grains; the retort was much less corroded than usual.

9. Thirty grains of this precipitate, distilled in a

VOL. IV. PART II.

glass retort with a drachm and an half of oil of vitriol, produced no siliceous earth on the water in the receiver, or that with which the earth wasedulcorated. The ley of fluorated volatile alkali was mixed with a solution of chalk in nitrous acid till no more precipitation took place. The mixture was passed through nitrous acid, and the precipitate adulcorated. It weighed, when dry, two drachms and 36 grains.

10. Two drachms of oil of vitriol being added to a drachm of this precipitate contained in a glass retort, the precipitate was attacked in the cold, but no crust appeared; the heat, however, was scarce applied, when the whole surface of the water was covered, and the same phenomena exhibited which are produced by the natural fluor.

11. Mr Scheele having observed that a mixture of fluor as transparent as mountain crystal, and oil of vitriol in a metallic cylinder, produced no appearance of siliceous earth on a wet sponge suspended in the inside, at Mr Meyer's request he made a new experiment, by adding oil of vitriol to portions of fluor of this transparent kind placed in two tin cylinders; some siliceous earth was put into one, and a wet sponge suspended in both. The next morning the sponge that was suspended over the cylinder which held the siliceous earth, was covered with the white powder, but no appearance of it was seen on the other. The experiment was repeated by Mr Meyer with the same result, but the white crust did not appear till after a night's standing.

12. A drachm of fluor, mixed with two of oil of vitriol, afforded, after a distillation of two hours, a thin film of lead on the surface of the water in the receiver, but no siliceous earth. The same mixture was afterwards distilled with the use only of a glass receiver instead of a lead one. In the beginning of the distillation a small spot appeared under the neck of the retort, and the neck itself was covered with white powder, but it soon disappeared; and though the empty part of the receiver was corroded, yet no more than half a grain of earth was procured.

These experiments so clearly point out the origin of the siliceous crust on the surface of the fluor acid, that its existence as a distinct acid is now universally allowed, even by those who formerly contended for its being only the vitriolic or some other acid disguised.—Experiments of a similar kind were made by Mr Wenzel, who performed his distillation in a leaden retort, furnished with a glass receiver. The water was covered with a variegated crust, and yielded a gelatinous precipitate with fixed alkali. On examining the receiver, he found its internal surface corroded, so that it appeared as if it had been rubbed with coarse sand. By substituting a leaden receiver, however, instead of a glass one, he obtained the acid entirely free from siliceous matter, and containing only a small quantity of iron and aluminous earth.

The fluor acid may also be procured by the nitrous, muriatic, and phosphoric acids.—Mr Scheele distilled one part of the mineral with two of concentrated nitrous acid. One part went over into the receiver along with the fluor acid, and a thick crust was formed on the water of the receiver. The mass remaining in the retort was calcareous earth saturated with nitrous acid.

Fluor Acid
and its
Combina-
tions.

With an equal quantity of marine acid, that of fluor passed over into the receiver with a large quantity of the muriatic: the internal surface of the receiver, as well as of the water contained in it, being covered with a white crust. The residuum was fixed sal ammoniac.

Phosphoric acid digested with powdered fluor, dissolved a good deal of it; and on distilling this solution, the fluor acid went over together with the watery particles of the mixture; the remaining mass in the retort had the properties of the ashes of bones.

The fluor acid procured in any of these ways is not distinguishable by the smell from that of sea-salt: in some cases it acts as muriatic acid, in others like that of tartar; but in most cases it shows properties peculiar to itself.

With fixed alkali the fluor acid forms a gelatinous and almost insipid matter, which refuses to crystallize. By evaporation a saline mass was obtained, which was in weight only the sixth part of the fixed alkali dissolved; did not change the colour of syrup of violets, but precipitated lime water, and likewise the solutions of gypsum and Epsom salt. With mineral alkali the same phenomena were produced as with the vegetable.

Volatile alkali with fluor acid formed likewise a jelly, which when separated from the liquor appeared to be siliceous earth. The clear liquid tasted like vitriolic ammoniac, and shot into very small crystals, which by sublimation yielded first a volatile alkali, and then a kind of acid sal ammoniac. By distillation with chalk and water, all the volatile alkali quickly came over. Lime water instantly threw down a regenerated fluor, which was the case also with solutions of lime in the nitrous and muriatic acids.—Solution of silver let fall a powder, which, before the blow-pipe, resumed its metallic form, the acid being dissipated, and forming a white spot on the charcoal round the reduced silver. Solution of quicksilver in nitrous acid was precipitated, and the powder was entirely volatile in the fire; but a solution of corrosive sublimate remained unchanged. Lead was totally precipitated from nitrous acid; and a solution of Epsom salt was rendered turbid. Oil of vitriol produced a fluor acid by distillation, which formed at the same time a thick crust on the water of the receiver. The regenerated fluor procured either by means of lime water or solutions of the earth in acids, was decomposed by fixed, but not by volatile alkali.

With lime, magnesia, and earth of alum, this acid became gelatinous. Part of the two last were dissolved.

Gold was not touched by the fluor acid either alone or mixed with that of nitre. Silver, in its metallic state, underwent no change. Its calx, precipitated by an alkali, was partly dissolved; but the remainder formed an insoluble mass at the bottom. Vitriolic acid expelled the fluor acid in its usual form. Quicksilver was not dissolved, but its calx precipitated from the nitrous solution was partially so. The remaining insoluble part of the calx united with the acid, and formed a white powder, from which the fluor acid was expelled by the vitriolic. The same powder formed, by means of the blow-pipe, a yellowish glass; which, however, evaporated by degrees, leaving a small glo-

bule of fixed glass behind. Lead was not dissolved, but the acid formed a sweet solution with its calx; from whence the latter could be precipitated by the acids of vitriol, and sea-salt, as also by sal ammoniac. On digesting a quantity of acid with calx of lead, which had been previously digested in the same, a spontaneous precipitation took place. The precipitate melted easily before the blow-pipe, and ran into metal; but part of the glass remained fixed in the fire. Copper was partially dissolved, as appeared by the blue colour assumed by the liquid on the addition of volatile alkali. The calx of copper was easily soluble; and the liquor, though gelatinous, yielded blue crystals, partly of a cubic and partly of an oblong form, from which the acid could not be separated but by heat. Iron was violently attacked, and gave out inflammable vapours during the solution. The liquor refused to crystallize; but, by evaporation, congealed into an hard mass after the moisture was dissipated; and from this mass the fluor acid might be expelled as usual by oil of vitriol. The same effect was also produced by heat alone; the acid rising in vapours, and leaving a red ochre behind. Calx of iron was also dissolved, and the solution tasted like alum; but it could not be reduced to crystals. Tin, bismuth, and regulus of cobalt, were not attacked in their metallic state; but the calces of all of them were soluble. Regulus of antimony and powdered antimony were not sensibly acted upon. Zinc produced the same effects as iron, excepting that the solution seemed more inclined to crystallize.

The most remarkable property of this acid, however, is its readily dissolving glass, and carrying it off in the form of vapour. This singular property belongs not only to the pure acid, but also to the ammoniacal salt formed by combining it with the volatile alkali. Mr Wiegleb informs us, that on evaporating to dryness, in a cup of Misnia porcelain, a solution of this kind of ammoniac, which by its smell showed an excess of volatile alkali, the glazing of the inside was entirely corroded, and the bottom left as rough as a file. During the evaporation the cup was covered with white paper, which when dry appeared full of small crystals of an acid taste, easily distinguishable by the naked eye. These, as well as the ammoniacal salt, powerfully attracted the moisture of the air.

This property of the fluor acid renders it extremely difficult to be kept. Mr Meyer informs us, that having kept some upwards of a year in a glass phial, it corroded the glass in many points surrounded with concentric circles, depositing a powder which adhered to the bottom. He is of opinion that golden vessels would be most proper for keeping this acid, as also for making experiments on the fluor itself. A phial covered in the inside with wax and oil has been recommended for the same purpose.

This acid, as well as those of vitriol, nitre, and sea-salt, has been exhibited by Dr Priestley in an aerial form. Having put some pounded spar into a phial, and poured oil of vitriol upon it, adopting at the same time the usual apparatus for obtaining air, he observed that a permanent cloud was formed by the vapour issuing out from the mouth of the tube, which he attributed to the attachment of the acid to the aqueous moisture of the atmosphere. The moment that water came

came in contact with this air, its surface became opaque and white by a stony film, which retarded the ascent of the water, till the air insinuating itself through the pores and cracks of the crust, the water necessarily rose as the air diminished; and breaking the crust, presented a new surface to the air, which was immediately covered with another crust. Thus one stony incrustation was formed after another till every particle of the air was united to the water; and the different films being collected and dried, formed a white powdery substance, generally a little acid to the taste; but when washed in much pure water, perfectly insipid. The property of corroding glass he found to belong to the fluor acid air only when hot. From some other experiments he concluded, that the fluor acid air was the same with what he had formerly obtained from vitriolic acid: but the experiments made since that time by various chemists, have now convinced him that it is an acid of a nature entirely different from all others.

Method of
engraving
on glass.

By means of the fluor acid, a new art has been discovered, viz. that of engraving upon glass. For this purpose a looking-glass plate is to be covered with melted wax or mastic; and when the coating becomes hard, it is to be engraved upon by a very sharp-pointed needle or other instrument of that kind. A mixture of oil of vitriol and fluor acid are then to be put upon the plate, and the whole covered with an inverted China vessel, to prevent the evaporation of the fluor acid. In two days the glass plate may be cleared of its coating, when all the traces of the needle will be found upon it.

§ 5. Of the SAL SEDATIVUS, or Acid of Borax.

858
Found in a
mineral in
Germany,
&c.

THIS is a saline substance of a very singular nature, and till lately found no where but in borax itself. Its origin in different parts of the world is related under the article BORAX; but since that article was printed, we have accounts of its being discovered in a mineral of a peculiar kind found at Lunenburg near Hartz. This is frequently transparent, but sometimes also a little opaque, and strikes fire slightly with steel. It has hitherto been found only in small crystals enveloped in a gypseous matter. These generally affect the cubical form, though they are sometimes irregular, and from the truncatures frequently appear to be of different kinds. One of them had fourteen faces, six small square planes, and eight hexahedral; though all these are modifications of cubes. Mr Wulstumb analyzed it with some difficulty; but at last found that 100 parts of the mineral contained 60 of sedative salt, ten of magnesia, and ten of calcareous earth; of clay and flint five parts, sometimes ten of iron, though frequently but five. The same acid has also been discovered in Peru, and a little in Hungary from an analysis of petroleum. This bitumen arises from a rock between Pecklenicza and Moscowina. It seems at first to be white, but soon grows black by exposure to the air. It was analysed by professor Winterl, who found it to contain a transparent oil in a butyraceous form, and a true sedative salt, united with the oil by means of an excess of phlogiston. The sedative salt was first discovered by Bechr, and afterwards more accurately described by Homberg; but its nature was at first very much misunderstood, being named the *narcotic salt of*

vitriol, on account of the vitriolic acid used in separating it from the borax. From this it is separable either by sublimation or crystallization. The method by sublimation is that recommended by Homberg. His process consists in mixing green vitriol with borax, dissolving them in water, filtering the solution, and evaporating till a pellicle appears: the liquor is then to be put into a small glass alembic, and the sublimation promoted till only a dry matter remains in the cucurbit. During this operation, the liquor passes into the receiver; but the internal surface of the capital is covered with a saline matter forming very small, thin, laminated crystals, very shining, and very light. This is the sedative salt. The capital is then to be unluted, and the adhering salt swept off with a feather; the part of the liquor which passed last into the receiver, is to be poured on the dry matter in the cucurbit; and a new sublimation is to be promoted as before, by distilling till the matter in the cucurbit is dry. These operations are to be frequently repeated in the same manner, till no more sedative salt can be obtained.

To obtain the sedative salt by crystallization, borax is to be dissolved in hot water; and to this solution any one of the three mineral acids is to be gradually added, by a little at a time, till the liquor be saturated, and even have an excess of acid, according to Mr Beaumé's process. The liquor is then to be left in a cold place; and a great number of small, shining, laminated crystals will be formed: these must be washed with a little very cold water, and drained upon brown paper. The sedative salt obtained by this process is somewhat denser than that obtained by sublimation; the latter being so light that 72 grains are sufficient to fill a large phial.

Sedative salt, though thus capable of being once sublimed, is not, however, volatile; for it arises only by means of the water of its crystallization; and when it has once lost its water by drying, it cannot be raised into vapours by the most violent fire, but remains fixed, and melts into a vitreous matter like borax itself. This glass is soluble in water, and then becomes sedative salt again. A great quantity of water is required to dissolve the sedative salt, and much more of cold than of boiling water; whence it is crystallizable by cold, as it also is by evaporation; a singular property, which scarce belongs to any other known salt.

This substance has not an acid, but a somewhat bitterish taste, accompanied with a slight impression of coolness. It nevertheless unites with alkaline salts as acids do, and forms with them neutral salts. It is soluble in spirit of wine, to which it communicates the property of burning with a green flame. It makes no change on the blue colour of vegetables, as other acids do. It expels the other acids from their bases, when distilled with a strong heat; though these are all capable of expelling it in the cold, the acid of vinegar not excepted.

The composition of sedative salt is very much unknown, as no means sufficient for its decomposition have hitherto been found out. Mr Bourdelin, who made many experiments on this salt, found that it was unalterable by treatment with inflammable matters, with sulphur, with mineral acids disengaged, or united with metallic substances, and with spirit of wine. He

ments.

could only perceive some marks of an inflammable matter, and a little marine acid. The former discovered itself by its communicating a sulphureous smell to the vitriolic acid employed; and the latter by a white precipitate formed in a solution of mercury in the nitrous acid, by the liquor which came over on distilling the salt with powdered charcoal.

Mr Cadet, in the Memoirs of the Royal Academy of Sciences for 1766, has given an account of some experiments made by him on borax and its acid: from which he infers (1), That the acid contained in borax itself is the marine, and not sedative, salt. (2.) That it is the marine, he proves by having made a corrosive sublimate with this acid and *mercurius precipitatus per se*. That sedative salt does not enter the composition of borax itself, he proves, by the impossibility of recomposing borax from uniting the sedative salt with fossil alkali. The salt so produced, he owns, is very like borax, but unfit for the purposes of soldering metals as borax is. He therefore thinks, that, in the decomposition of borax, the principles of the salt are somewhat changed, by the addition of that acid which extricates the sedative salt; and that this salt is composed of the marine acid originally existing in the borax, of the vitriolic acid employed in the operation, and of a vitrescible earth. (If this is true, then sedative salt either cannot be procured by any other acid than the vitriolic, or it must have different properties according to the acid which procures it.) The vitrescible earth, he says, is that which separates from borax during its solution in water, and which abounds more in the unrefined than refined borax, and which he thinks consists of a calx of copper, having obtained a regulus of copper from it. As he has never been able, however, to compose borax by the union of these ingredients, his experiments are by no means decisive. Mr Beaumé has asserted that it is always produced by rancid oils; but Dr Black thinks his proofs by no means satisfactory.

Sedative Salt COMBINED,

I. *With Vegetable Alkali.* This salt forms a compound very much resembling borax itself in quality; but in what respects it differs from, or how far it is applicable to, the purposes of borax, hath not yet been determined.

863
Borax.

II. *With Mineral Alkali.* This salt has generally been thought to recompose borax: and though Mr Cadet has denied this, yet as his experiments are hitherto imperfect and unsupported, we shall here give the history of that salt, as far as it is yet known.

This salt is prepared in the East Indies. It is said, that from certain hills in these countries there runs a green saline liquor, which is received in pits lined with clay, and suffered to evaporate with the sun's heat; that a bluish mud which the liquor brings along with it is frequently stirred up, and a bituminous matter, which floats upon the surface, taken off; that when the whole is reduced to a thick consistence, some melted fat is mixed, the matter covered with vegetable substances and a thin coat of clay; and that when the salt has crystallized, it is separated from the earth by a sieve. In the same countries is found native the mineral alkali in considerable quantity; sometimes tolerably pure, at other times blended with he-

terogeneous matters of various kinds. This alkali appears to exist in borax, as a Glauber's salt may be formed from a combination of borax with vitriolic acid. For a further account See BORAX.

Borax, when imported from the East Indies, consists of small, yellow, and glutinous crystals. It is refined, some say, by dissolving it in lime-water; others, in alkaline lixivium, or in a lixivium of caustic alkali; and by others, in alum-water. Refined borax consists of large eight-sided crystals, each of which is composed of small, soft, and bitterish scales. It has been said that crystals of this size can by no means be obtained by dissolving unrefined borax in common water; that the crystals obtained in this way are extremely small, and differ considerably from the refined borax of the shops; insomuch that Cramer calls the large crystals, not a purified, but an adulterated borax. When dissolved in lime-water, the borax shoots into larger crystals; and largest of all, when the vessel is covered, and a gentle warmth continued during the crystallization. All this, however, is denied by Dr Black; who says, that in order to accomplish the purification, we have only to dissolve the impure borax in hot water; to separate the impurities by filtration, after which the salt shoots into the crystals we commonly see. During the dissolution, borax appears glutinous, and adheres in part to the bottom of the vessel. From this glutinous quality, peculiar to borax among the salts, it is used by dyers for giving a gloss to silks.

All acids dissolve borax slowly, and without effervescence. It precipitates from them most, but not all, metallic substances; along with which a considerable part of the borax is generally deposited. It does not absorb the marine acid of luna cornea, or of mercury sublimate. It melts upon the surface of the former without uniting, and suffers the latter to rise unchanged: the borax in both cases becomes coloured; in the first, milky with red streaks; in the latter, amethyst or purple. Mixed with sal ammoniac, it extricates the volatile alkali, and retains the acid; but mixed with a combination of the marine acid with calcareous earths, it unites with the earth, and extricates the acid. It extricates the acid of nitre without seeming to unite with the alkaline basis of that salt; nor does it mingle in fusion with the common fixed alkaline salts, the borax flowing distinct upon their surface. A mixture of borax with twice its weight of tartar, dissolves in one sixth of the quantity of water that would be necessary to dissolve them separately: the liquor yields, on inspissation, a viscous, tenacious mass like glue; which refuses to crystallize, and which deliquesces in the air. Borax affords likewise a glutinous compound with the other acids, except the vitriolic; whence this last is generally preferred for making the sedative salt. It proves most glutinous with the vegetable, and least with the marine. With oils, both expressed and distilled, it forms a milky, semi-saponaceous compound. It partially dissolves in spirit of wine. In conjunction with any acid, it tinges the flame of burning matters green; the precipitate thrown down by it from metallic solutions has this effect. It does not deflagrate with nitre. Fused with inflammable matters, it yields nothing sulphureous, as those salts do which

tions

864

Refined.

865

Its proper-
ties.

Acetous Acid and its Combinations. which contain vitriolic acid. By repeatedly moistening it when considerably heated, it may be entirely sublimed.

Borax retains a good quantity of water in its crystals; by which it melts and swells up in a heat insufficient to vitrify it. It is then spongy and light, like calcined alum; but, on increasing the fire, it flows like water.

§ 6. Of the Acetous Acid and its Combinations.

867
How procured.

THIS acid is plentifully obtained from all vinous liquors, by a fermentation of a particular kind. (see FERMENTATION, and VINEGAR.) It appears first in the form of an acid liquor, more or less deeply coloured, as the vinegar is more or less pure. By distillation in a common copper-still, with a pewter head and worm, this acid may be separated from many of its oily and impure parts. Distilled vinegar is a purer but not a stronger acid than the vinegar itself; for the acid is originally less volatile than water, though, by certain operations, it becomes more so. After vinegar has been distilled to about $\frac{1}{8}$ of its original bulk, it is still very acid, but thick and black. This matter continues to yield, by distillation, a strong acid spirit, but tainted with an empyreumatic oil. If the distillation is continued, a thick black oil continues to come over; and at last some volatile alkali, as in the distillation of animal substances. The caput mortuum left in the distilling vessel, being calcined in an open fire, and afterwards lixiviated, yields some fixed alkaline salt.

Acetous Acid COMBINED,

868
Sal diureticus.

I. *With Vegetable Alkali.* The produce of this combination is the *terra foliata tartari*, or sal diureticus of the shops; but to prepare this salt of a fine white flaky appearance, which is necessary for sale, is a matter of some difficulty. The best method of performing this operation is, after having saturated the alkali with the vinegar, which requires about 15 parts of common distilled vinegar to one of alkali, to evaporate the liquor to dryness; then melt the saline mass which remains with a gentle heat; after which it is to be dissolved in water, then filtered, and again evaporated to dryness. If it is now dissolved in spirit of wine, and the liquid abstracted by distillation, the remaining mass being melted a second time, will, on cooling, have the flaky appearance desired.

A good deal of caution is necessary in the first melting; for the acetous acid is easily dissipable, even when combined with fixed alkali, by fire. It is proper, therefore, that, when the salt is melted, a little should be occasionally taken out, and put into water; and, when it readily parts with its blackness to the water, must then be removed from the fire. The salt, when made, has a very strong attraction for water, inasmuch that it is not easily preserved, even when put into glass bottles. To keep it from deliquating, Dr Black, therefore, recommends the corks to be covered with some bituminous matter; otherwise they would transmit moisture enough to make the salt deliquescent.

869
Acetous acid with fossil alkali.

II. *With Fossil Alkali.* This alkali, combined with the acetous acid, forms a salt whose properties are not well known. Dr Lewis affirms, that it is nearly similar

to the *terra foliata tartari*. The author of the Chemical Dictionary, again, maintains it to be quite different: particularly that it crystallizes well, and is not deliquescent in the air; whereas the former cannot be crystallized; and even when obtained in a dry form, unless great care is taken to exclude the air, will presently deliquescent.

III. *With Volatile Alkali.* This combination produces a salt so exceedingly deliquescent, that it cannot be procured in a dry form without the greatest difficulty. In a liquid state, it is well known in medicine, as a sudorific, by the name of *spiritus mindereri*. It may, however, be procured in a dry form, by mixing equal parts of vitriolic sal ammoniac and *terra foliata tartari*, and subliming the mixture with a very gentle heat. When the salt is once procured, the utmost care is requisite to preserve it from the air.

IV. *With Earths.* Combinations of this kind are but little known. With the calcareous and argillaceous earths compounds of an astringent nature are formed. According to the author of the Chemical Dictionary, the salt resulting from a combination of vinegar with calcareous earth easily crystallizes, and does not deliquescent. With magnesia the acetous acid does not crystallize; but, when inspissated, forms a tough mass, of which two drachms, or two and a half, are a brisk purgative.

V. *With Copper.* Upon this metal the acid of vinegar does not act briskly, until it is partly at least calcined. If the copper is previously dissolved in a mineral acid, and then precipitated, the calx will be readily dissolved by the acetous acid. The solution is of a green colour, and beautiful green crystals may be obtained from it. The solution, however, is much more easily effected, by employing verdigris, which is copper already united with a kind of acetous or tartareous acid, and very readily dissolves in vinegar. The crystals obtained by this process are used in painting, under the name of *distilled verdigris*.

The most ready, and in all probability the cheapest, method of preparing the crystals of verdigris is that proposed by Mr Wenzel, by mixing together the solutions of sugar of lead and blue vitriol, when an exchange of bases takes place; the lead being instantly precipitated by the vitriolic acid, and the acetous acid uniting with the copper. From 15 ounces and two drachms of sugar of lead with twelve ounces of blue vitriol, five ounces of the crystals were obtained. The precipitate of lead, though washed several times with water, never lost its green colour. It may either be used, he says, in this state, as a green pigment, or it may be made perfectly white by digestion in dilute nitrous acid.

VI. *With Iron.* Vinegar acts very readily upon iron, and dissolves it into a very brown and almost black liquor, which does not easily crystallize, but, if inspissated, runs per deliquium. This liquor is employed in the printing of linens, calicoes, &c. being found to strike a finer black with madder, and to injure the cloth less, than solutions of iron in the other acids.

VII. *With Lead.* The acetous acid dissolves lead in its metallic state very sparingly; but if the metal is calcined, it acts upon it very strongly. Even after lead is melted into glass, the acetous acid will receive a strong impregnation from it; and hence it is dangerous

tions.

to put vinegar into such earthen vessels as are glazed with lead. In the metallic state, only a drachm of lead can be dissolved in eight ounces of distilled vinegar.

875
Cerufs.

If lead is exposed to the vapours of warm vinegar, it is corroded into a kind of calx, which is used in great quantities in painting, and is known by the name of *cerufs*, or *white lead*. The preparation of this pigment has become a distinct trade, and is practised in some places of this kingdom where lead is procurable at the lowest price. The process for making cerufs is thus given by the author of the Chemical Dictionary.

"To make cerufs, leaden plates rolled spirally, so that the space of an inch shall be left between each circumvolution, must be placed vertically in earthen pots of a proper size, containing some good vinegar. These leaden rolls ought to be so supported in the pots that they do not touch the vinegar, but that the acid vapour may circulate freely betwixt the circumvolutions. The pots are to be covered, and placed in a bed of dung, or in a sand-bath, by which a gentle heat may be applied. The acid of vinegar being thus reduced into vapour, easily attaches itself to the surface of these plates, penetrates them, and is impregnated with the metal, which it reduces to a beautiful white powder, called *cerufs*. When a sufficient quantity of it is collected on the plates, the rolls are taken out of the pots, and unfolded; the cerufs is then taken off, and they are again rolled up, that the operation may be repeated.

"In this operation, the acid being overcharged with lead, this metal is not properly in a saline state; hence cerufs is not in crystals, nor is soluble in water: but a saline property would render it unfit for painting, in which it is chiefly employed."

876
Observa-
tions on the
process for
cerufs.

Though this process may in general be just, yet there are certainly some particulars necessary to make cerufs of a proper colour, which this author has omitted; for though we have carefully treated thin plates of lead in the manner he directs, yet the calx always turned out of a dirty grey colour. It is probable, therefore, that after the lead has been corroded by the steam of vinegar, it may be washed with water slightly impregnated with the vitriolic and nitrous acids.

This preparation is the only white hitherto found fit for painting in oil: but the discovery of another would be very desirable, not only from the faults of cerufs as a paint, but also from its injuring the health of persons employed in its manufacture, by affecting them with a severe colic; which lead, and all its preparations, frequently occasion.

877
Sugar of
lead.

If distilled vinegar is poured on white lead, it will dissolve it in much greater quantity than either the lead in its metallic form, or any of its calces. This solution filtered and evaporated, shoots into small crystals of an austere sweetish taste, called *sugar of lead*. These are used in dyeing, and externally in medicines. They have been even given internally for spitting of blood. This they will very certainly cure; but at the same time they as certainly kill the patient by bringing on other diseases. If these crystals are repeatedly dissolved in fresh acids, and the solutions evaporated, an oily

kind of substance will at last be obtained, which can scarcely be dried.

From all the metallic combinations of the acetous acid, it may be recovered in an exceedingly concentrated form, by simple distillation, sugar of lead only excepted. If this substance is distilled in a retort with a strong heat, it hath been said that an inflammable spirit, and not an acid, comes over; but this is denied by Dr Black.

VIII. *With Tin*. The combination of acetous acid with tin is so little known, that many have doubted whether distilled vinegar is capable of dissolving tin or not. Dr Lewis observes, "That plates of pure tin put into common vinegar begun in a few hours to be corroded, without the application of heat. By degrees a portion of the metal was taken up by the acid, but did not seem to be perfectly dissolved, the liquor appearing quite opaque and turbid, and depositing great part of the corroded tin to the bottom, in a whitish powder. A part of the tin, if not truly dissolved, is exquisitely divided in the liquor: for, after standing many days, and after passing through a filter, so much remained suspended as to give a whiteness and opacity to the fluid. Acid juices of fruits, substituted to the vinegar, exhibited the same phenomena. These experiments are not fully conclusive for the real solubility of tin in these acids, with regard to the purposes for which chemists have wanted such a solution: but they prove what is more important; that tin, or tinned vessels, however pure the tin be, will give a metallic impregnation to light vegetable acids suffered to stand in them for a few hours."

With regard to other metallic substances, neither the degree of attraction which the acetous acid has for them, nor the nature of the compounds formed by the union of it with such substances, are known; only, that as much of the reguline part of antimony is dissolved in this acid as to give it a violent emetic quality. See *Regulus of Antimony*.

Concentration of the *Acetous Acid*.

Common vinegar, as any other weak acid, may be advantageously concentrated by frost; as also may its spirit or the distilled vinegar of the shops: but as the cold, in this country, is seldom or never so intense as to freeze vinegar, this method of concentration cannot be made use of here. If distilled vinegar be set in a water-bath, the most aqueous part will arise, and leave the more concentrated acid behind. This method, however, is tedious, and no great degree of concentration can be produced, even when the operation is carried to its utmost length. A much more concentrated acid may be obtained by distilling in a retort the crystals of copper, mentioned (no 872.) under the name of *distilled verdegris*. A very strong acid may thus be obtained, which has a very pungent smell, almost as suffocating as volatile sulphureous acid. The Count de Lauraguais discovered that this spirit, if heated in a wide-mouthed pan, would take fire on the contact of flaming substances, and burn entirely away, like spirit of wine, without any residuum. The same nobleman also observed, that this spirit, when well concentrated, easily crystallizes without ad-

Acetous Acid and its Combinations.

This may seem to be the most proper method of obtaining the acetous acid in its greatest degree of strength and purity: but as the process requires a very strong heat to be used towards the end of the operation, it is probable that part of the acetous acid may be by that means entirely decomposed. It would seem preferable, therefore, to decompose pure terra foliata tartari by means of the vitriolic acid, in the same manner as nitre or sea-salt are decomposed for obtaining their acids. In this case, indeed, the acetous acid might be a little mixed with the vitriolic; but that could easily be separated by a second distillation. A still better method of preparing this acid seems to be by distilling sugar of lead with oil of vitriol. The proportion used by M. Lorenzen of Copenhagen, is three ounces of vitriolic acid to eight of the sugar of lead. Mr Dollfus recommends two parts of sugar of lead to one of vitriolic acid.

883
Dr Priestley's experiments.

Dr Priestley, who gives us several experiments on the vegetable acid when reduced to the form of air, mentions his being easily able to expel it from some exceedingly strong concentrated vinegar, by means of heat alone. This seems somewhat contrary to the count de Lauragnais's observation of the disposition of the *spirit of verdegris*, as it is commonly called, to crystallize; but a still greater difference is, that the vegetable acid air extinguished a candle, when, according to the Count's observation, it ought to have been inflammable. The most curious property observed by Dr Priestley is, that the vegetable acid air being imbibed by oil olive, the oil was rendered less viscid, and clearer, *almost like an essential oil*. This is an useful hint; and, if pursued, might lead to important discoveries.

Acetous acid combined with Inflammable Matter.

884
Vegetable ether.

The only method yet known, of combining acetous acid with the principle of inflammability, is by mixing together equal parts of the strongly concentrated acid called *spirit of verdegris*, and spirit of wine. The result is, a new kind of ether, similar to the vitriolic, nitrous, and marine. This ether, however, retains some of the acidity and peculiar smell of the vinegar. By rectification with fixed alkali, it may be freed from this acidity, and then smells more like true ether, but still retaining something of the smell, not of the acid, but the inflammable part of the vinegar.

In this process a greater quantity of ether is obtained than by employing the vitriolic acid; which shows that the vegetable acid is essentially fitter to produce ether than the vitriolic. For making the acetous ether readily, Mr Dollfus recommends eight ounces of sugar of lead dried by a very gentle heat, until it loses the water of crystallization, when it will weigh five ounces and six drachms. It is then to be put into a glass retort, and a mixture of five ounces of vitriolic acid, with eight of spirit of wine, poured upon it, and the whole distilled with a very gentle fire. The first ounce that passes over will be dulcified acetous acid, the next almost all ether, and the third ether in its purest state.

An ether may also be obtained from vinegar of wood. To make it, the most concentrated acid of this kind is to be made use of. For this purpose an em-

pyreumatic acid must first be distilled from beech-wood, and then rectified by a second distillation. Three pounds of this require for their saturation five ounces of purified alkali, which by evaporation and fusion affords three ounces and a quarter of terra foliata tartari. From this, one ounce six drachms of concentrated acid are obtained; and this, on being mixed with an equal quantity of alcohol, yields two ounces one drachm and a half of genuine ether.

Acid of Tartar and its Combinations.

§ 7. Of the Acid of TARTAR.

TARTAR is a substance thrown off from wine, after it is put into casks to depurate. The more tartar that is separated, the more smooth and palatable the wine is. This substance forms a thick hard crust on the sides of the casks: and, as part of the fine dregs of the wine adhere to it, the tartar of the white wines is of a greyish white colour, called *white tartar*; and that of red wine has a red colour, and is called *red tartar*.

885
Tartar.

When separated from the casks on which it is formed, tartar is mixed with much heterogeneous matter; from which, for the purposes of medicine and chemistry, it requires to be purified. This purification is performed at Montpellier; and consists first in boiling the tartar in water, filtering the solution, and allowing the salt to crystallize, which it very soon does; as tartar requires nearly twenty times its weight of water to dissolve it.

886
Cream of tartar.

The crystals of tartar obtained by this operation are far from being perfectly pure; and therefore they are again boiled in water, with an addition of clay, which absorbs the colouring matter; and thus, on a second crystallization, a very pure and white salt is obtained. These crystals are called *cream*, or *crystals of tartar*; and are commonly sold under these names.

Dr Black observes, that in the purification of tartar, it is necessary to add some earthy substances, in order to absorb or carry down the colour. Macquer thinks that these substances unite in part with the tartar, and render it more soluble, but they have little disposition to unite with acids; they are the purer kinds of clay, and promote the complete deposition of its impurities: so that in the management of wines it is necessary to add certain powdery substances which have some weight, and fall to the bottom readily; and which, in falling, carry down a number of particles that would otherwise float in the liquor for a long time, being so light that they could hardly be made to subside; but the particles of clay adhering to them increase their gravity; and probably it answers the same purpose in the refinement of tartar.

To obtain the pure Acid of Tartar.

For a long time the cream or crystals of tartar were considered as the purest acid which could be obtained from this substance; but, in the year 1770, an analysis of tartar was published in the Swedish transactions, by Mr Scheele. His method of decomposing the salt was, to dissolve it in a sufficient quantity of boiling water, then to add chalk in fine powder till the effervescence ceased. A copious precipitation ensued; and the remaining liquor being evaporated,

887
Scheele's analysis of cream of tartar.

Acid of
Tartar and
its Combi-
nations.

porated, afforded a soluble tartar. This proved, that cream of tartar is not, as was commonly supposed, an acid of a peculiar kind, joined with a great deal of earthy impurities; but really a compound salt, containing an alkali joined with an acid; and that the alkali produced from burnt tartar is not generated in the fire, but pre-existent in the salt.

The whole sediment obtained in this experiment, is the calcareous earth combined with the acid of tartar, which may justly be called *selenites tartareus*. If some diluted vitriolic acid is poured upon this *selenites tartareus*, the vitriolic acid expels the acid of tartar, forming a true selenite with the earth, while the liquor contains the pure acid of tartar. By inspissation this acid may be made stronger, and even formed into small white crystals, which do not deliquesce in the air. A particular species of tartar extracted from sorrel hath been sold for taking spots out of cloths, under the name of *essential salt of lemons*, and which is now discovered to be the same with the acid of sugar.

888
Essential
salt of le-
mons.

This experiment was soon after confirmed by Dr Black; who farther observed, that if quicklime was used instead of chalk, the whole acid would be absorbed by the lime, and the remaining liquor, instead of being a solution of soluble tartar, would be a caustic lixivium. The most ready method, however, of procuring the pure acid of tartar seems to be that recommended by Mr Schiller in the Chemical Annals for 1787. One pound of cream of tartar is to be boiled in five or six pounds of water, and a quarter of a pound of oil of vitriol added by little and little, by which means a perfect solution will be obtained. By continuing the boiling, all the vitriolated tartar is precipitated. When the liquor is evaporated to one half, it must be filtered; and if, on the renewal of the boiling, any thing farther is precipitated, the filtration is to be repeated. The clear liquor is then to be reduced to the consistence of a syrup, and set in a temperate, or rather a warm place, when very fine crystals will be formed, and as much acid obtained as is equal in weight to half the cream of tartar employed. If too small a quantity of vitriolic acid has been employed, the undecomposed cream of tartar falls along with the vitriolated tartar.

Acid of Tartar COMBINED,

889
Soluble tar-
tar.

I. *With Vegetable Alkali.* If the pure acid of tartar be combined with this alkali to the point of saturation, a neutral salt is produced, which deliquesces in the air, and is not easily crystallized, unless the liquor be kept warm, and likewise be somewhat alkaline. This salt, called *soluble tartar*, is used in medicine as a purgative; but as its deliquescence does not admit of its being kept in a crystalline form, it is always sold in powder. Hence those who prepare soluble tartar, take no further trouble than merely to rub one part of fixed alkaline salt with three of cream of tartar, which renders the compound sufficiently neutral, and answers all the purposes of medicine. Dr Black informs us, that in medical prescriptions, where soluble tartar is ordered as a purgative along with a decoction of tamarinds, the acid of the latter will decompose the soluble tartar, and thus the prescription may perhaps be rendered ineffectual. The saline mixture used in fevers is nothing but a *tartarus solubilis* in solution.

According to Mr Scheele, cream of tartar may be
No 73.

recomposed from the pure acid and alkali in the following manner: "Upon fixed vegetable alkali pour a solution of the acid of tartar. Continue this till the effervescence is over; the fluid will then be transparent; but if more of the acid is added, it will become turbid and white, and small crystals like white sand will be formed in it. These crystals are a perfect cream of tartar.

Acid of
Tartar and
its Combi-
nations.

890
Regenera-
ted cream
of tartar.

Upon these principles, another method of decomposing cream of tartar might be tried; namely, adding to it as much oil of vitriol as would saturate the alkali, then dissolving and crystallizing the salt: but, by this method, there would be danger of the acid being adulterated with vitriolated tartar.

II. *With Fossile Alkali.* The salt produced from an union of cream of tartar with fossile alkali, has been long known under the names of *Seignette's salt*, *sal Rupellensis*, or *Rochelle salt*; but as the cream of tartar is now discovered to be not a pure acid, but adulterated with a portion of soluble tartar, possibly some differences might be observed if the pure acid was used.

891
Seignette's
or Rochelle
salt.

This salt was first invented and brought into vogue by one Seignette, an apothecary at Rochelle, who kept the composition a secret as long as he could. Messrs Boylue and Geoffroy afterwards discovered and published its composition.

To prepare this salt, crystals of mineral alkali are to be dissolved in hot water, and powdered cream of tartar thrown in as long as any effervescence arises. For the better crystallization of the salt, the alkali ought to prevail. The liquor must then be filtered and evaporated, and very fine large crystals may be obtained by cold, each of which is the half of a polygonous prism cut in the direction of its axis. This section, which forms a face much larger than the rest, is, like them, a regular rectangle, distinguishable from the others, not only by its breadth, but also by two distinct diagonal lines which intersect each other in the middle. The following method of preparing Seignette's salt, recommended by Mr Scheele, seems preferable to any other on account of its ease and cheapness. Thirty six ounces of crystals of tartar are to be saturated with potash, and eleven ounces of common salt dissolved in the ley. When it is grown cold, and the vitriolated tartar has subsided to the bottom, it is filtered and evaporated till a pellicle appears; the two first crystallizations yield a fine Seignette's salt; the third contains some digestive salt; and the fourth is entirely composed of it. The reason of this formation of Seignette's salt is, that the vegetable alkali has a greater attraction for acids than the mineral, and therefore decomposes the sea-salt, whose basis is then at liberty to combine with the acid of tartar; while the stronger marine acid takes the vegetable alkali.—A salt of the same kind will be produced by adding Glauber's salt instead of common sea-salt.

III. *With Volatile Alkali.* With regard to this combination, all we know as yet is, that if the alkali is over-saturated with acid, a cream of tartar, almost as difficult of solution as that of fixed alkali, will be obtained. When the saturation has been pretty exact, a beautiful salt, composed of four sided pyramids, and which does not deliquesce in the air, is produced. It is instantly decomposed, and emits a pungent volatile smell on being mixed with fixed alkali.

IV. *With Earths.* All that is as yet known concerning these combinations, is, that with the calcareous earth a compound not easily soluble in water is formed. The other properties of this substance, and the nature of combinations of tartareous acid with other earths, are entirely unknown.

V. *With Copper.* In its metallic state, cream of tartar acts but weakly on this metal, but dissolves verdigris much more perfectly than distilled vinegar can. The solution with cream of tartar, being evaporated, does not crystallize, but runs into a gummy kind of matter; which, however, does not attract the moisture of the air. It readily dissolves in water, and makes a beautiful bluish green on paper, which has the property of always shining, as if covered with varnish. The effects of the pure acid on this metal have not yet been tried.

VI. *With Iron.* The effects of a combination of iron with the pure acid have not hitherto been tried. Cream of tartar dissolves this metal into a green liquor, which being evaporated runs *per deliquium*. It has been attempted to substitute a solution of this kind to the liquor used in printing calicoes formed of iron and four beer; but this gave a very dull brownish colour with madder. Possibly, if the pure acid was used, the colour might be improved. In medicine, a combination of cream of tartar with iron is used, and probably may be an useful chalybeate.

VII. *With Regulus of Antimony.* See Sect. III.

§ 8. Of the Acid of SUGAR.

THAT sugar contains an acid, which on distillation by a strong fire arises in a liquid form, in common with that of most other vegetable substances, has been generally known; but how to obtain this acid in a concrete form, and to appearance as pure and crystallizable as the acid of tartar, we were entirely ignorant, till the appearance of a treatise intitled, *Dissertatio Chemica, de acido Sacchari, auctore Johanne Afzelio Arvidsson, 4to, Upsalæ.*

Of the method of procuring, and the properties of, this new acid, we have the following account in the *Edinburgh Medical Commentaries*, vol. iv.

“1. To an ounce of the finest white sugar in powder, in a tubulated retort, add three ounces of strong spirit of nitre.

“2. The solution being finished, and the phlogiston of the spirit of nitre mostly exhaled, let a receiver be properly fitted to the retort and luted, and the liquor then made to boil gently.

“3. When the solution has obtained a brownish colour, add three ounces more of spirit of nitre, and let the ebullition be continued till the fumes of the acid are almost gone.

“4. The liquor being at length emptied into a larger vessel, and exposed to a proper degree of cold, quadrangular prismatic crystals are observed to form; which being collected, and dried on soft paper, are found to weigh about 100 grains.

“5. The remaining liquor being again boiled in the same retort, with two ounces of fresh spirit of nitre, till the red vapours begin to disappear, and being then in the same manner exposed to crystallize, about 43 grains of saline spiculæ are obtained.

VOL. IV. Part II.

“6. To the liquid that still remains, about two ounces more of spirit of nitre being added, and afterwards the whole being, *both by boiling and evaporation*, reduced to a dry mass, a brown, saline, gelatinous kind of substance is produced, which, when thoroughly dry, is found to weigh about half a drachm.

“In the same manner, a similar acid, we are told, may be obtained from different saccharine substances, as *gum-arabic, honey, &c.*; but from none in such quantities, or so pure, as from fine sugar.”

This salt possesses some very singular properties, of which what appears to us the most remarkable, and which we cannot help reading with some degree of doubt, is, that it produces an effervescence on being added to such *alkaline, earthy, or metallic substances, as contain the vitriolic acid*. From this we should be apt to think, that this acid was capable of dislodging even the vitriolic acid from its basis.

Acid of sugar, being distilled in a retort, gives over about $\frac{1}{10}$ of its weight of water. By an intense heat it melts, and is partly sublimed; leaving in the retort a dark grey mass, of about the fifth part of the weight of the crystals made use of. The sublimed salt easily recovers its crystalline form, and seems to have undergone no further change by sublimation than being rendered more pure. During the distillation a great quantity of elastic vapour rushes out (about 100 cubic inches from half an ounce of the crystals), which, from the distilled liquor's precipitating lime-water, we may judge to be fixed air. In a second sublimation, white fumes are sent over, which, when cold, appear to be an acid, glassy-coloured liquor, but cannot be again crystallized. “Such parts of the salts as adhere to the sides and necks of the vessels do not appear to be in the least changed in the process.” On a third sublimation, these parts produced such elastic vapours as burst the receiver.

This singular salt has a considerable acid power; twenty grains of it giving a very considerable degree of acidity to a large tankard of water. It dissolves in an equal weight of distilled water, but concretes on the liquor's growing cool. It is also soluble in spirit of wine; 100 parts of boiling spirit of wine dissolving 56 of the saccharine crystals, but no more than 40 when cold. The solution in spirit of wine soon becomes turbid; and deposits a mucous sediment, in quantity about $\frac{1}{10}$ of the acid made use of. When cold, irregular scaly crystals are formed, which when dry are perfectly white.

With vegetable alkali, the acid of sugar can scarcely be formed into crystals, unless either the alkali or acid predominate. With mineral alkali, a salt very difficult of solution is formed. The quantity of volatile alkali saturated by this acid is incredible. “Six parts of a pure volatile alkali may be saturated with one of the acid of sugar. The produce is a quadrangular prismatic salt. With lime this acid unites so strongly, as to be separable by no other means than a strong heat. What kind of a salt results from this combination we are not told; but the author is of opinion, that this shows the use of lime in the purification of sugar, in order to absorb the superfluous acid. Being saturated with some of the *terra ponderosa*, the acid of sugar immediately deposits a quantity of pellucid angular crystals, scarcely soluble in water. With magne-

3 R

fia

Acid of Sugar and its Combinations.

When the salt appears in form of a white powder, soluble neither in water nor spirit of wine, unless the acid prevails. It has a stronger affinity with magnesia than any of the alkaline salts. With earth of alum, no crystals are obtained; but a yellow pellucid mass, of a sweetish and somewhat astringent taste; which, in a moist air, liquefies, and increases two-thirds in weight.

901
Its effects on metals.

This acid acts upon all metals, gold, silver, platina, and quicksilver, not excepted, if they have been previously dissolved in an acid, and then precipitated. Iron in its metallic state is dissolved in very large quantity by the saccharine acid; 45 parts of iron being soluble in 55 of acid. By evaporation, the liquor shoots into yellow prismatic crystals, which are easily soluble in water. With cobalt, a quantity of yellow-coloured crystals are obtained, which being dissolved in water, and sea-salt added to the solution, form a sympathetic ink. The elective attractions of this singular acid are, first, lime, then the *terra ponderosa*, magnesia, vegetable alkali, mineral alkali, and lastly clays. With spirit of wine an ether was obtained, which cannot easily be set on fire unless previously heated, and burns with a blue instead of a white flame.

902
Saccharine ether.

903
Whether this acid is produced from the nitrous.

Towards the conclusion of his dissertation the author observes, that some may imagine that the acid of nitre, made use of in these experiments, may have a considerable share in the production of what he has termed *acid of sugar*. But though he acknowledges that this acid cannot in any way be obtained but by the assistance of spirit of nitre, he is thoroughly convinced that it does not, in any degree, enter into its composition.

What occurs to us on this subject is, that if the acid really pre-exists in the sugar, it must give some tokens of its existence by mixing the sugar with other substances besides spirit of nitre. The author himself thinks that lime acts upon the acid part of the sugar: from whence we are apt to conclude, that by mixing lime, in a certain proportion, with sugar, a compound should be obtained somewhat similar to what was formed by a direct combination of lime with the pure acid. In this case, we might conclude that the nitrous acid produces this salt, by combining with the inflammable part of the sugar, becoming thereby volatile, and flying entirely off, so as to leave the acid of the sugar pure. In the distillation of dulcified spirit of nitre, however, we have an instance of the nitrous acid itself being very much altered. This must therefore suggest a doubt, that the acid salt obtained in the present case is only the nitrous acid deprived of its phlogiston, and united with some earthy particles.

2d 903
The same with the acid of sorrel.

In a treatise lately published by Mr Rigby, however, we are informed that sugar itself may be recomposed by uniting the acid of sugar with phlogiston; which assertion, if well founded, undoubtedly decides the dispute in favour of the saccharine acid being originally contained in the sugar. Late experiments have determined it to be the same with that of sorrel; for which, as well as many other valuable acquisitions, the science of chemistry is indebted to Mr Scheele. Having dissolved as much acid of sugar in cold water as the liquor could take up, he added to this solution

some lixivium of tartar drop by drop, waiting a little after each drop and found the mixture, during the effervescence, full of small crystals, which were genuine salt of wood-sorrel. M. Klaproth having precipitated a nitrous solution of quicksilver with salt of wood-sorrel, perfectly neutralized by vegetable alkali, obtained a white precipitate; which, whenedulcorated and dried, and gently heated in a tea-spoon, fulminated with a noise not inferior to that of fulminating gold. Acid of sugar perfectly neutralized with vegetable alkali, afforded the same precipitate, and fulminated in the same manner.

Acid of Phosphorus and its Combinations.

3d 903
Fulminating quicksilver.

§ 9. Of the Acid of PHOSPHORUS.

This acid was first discovered by Homberg in urine; afterwards by Margraaf in mustard and cruciferous plants: M. Bochante discovered it in wheat; and lastly, M. Hassenfratz has traced it in the mineral kingdom with great attention.—He has found that phosphorated iron is contained in all the Prussian blues, when not purified; but that this acid is produced by the coals employed in the process, and is no constituent part of the tinging matter. According to him it occurs almost universally in the minerals of iron which are found in the slimy strata of the earth, as well as those which are undoubtedly modern, whether primary or secondary; unless the iron be so far of a metallic nature as to be attracted by the magnet, or very near that state. It is afforded by the ochry strata, and those which contain hæmatites as well as the slimy kind. Into these it is supposed to have come by the decomposition of vegetables; and to investigate this matter he examined the *hibiscus palustris*, *solidago*, *virga aurea*, *antirrhinum*, *lunaria*, *solanum nigrum*, *vulgatum*, *stachys palustris*, *artemisia Zeylandica*, *ruta graveolens*, *lycopus Europeus*, *carex acuta*; *vinca major*, *nepeta Pannonica*, and *noa Abyssina*. All these plants afforded the acid of wood-sorrel and the phosphoric acid. The quantity of the former varied from two ounces two drachms 18 grains of acid salt containing some calcareous earth, to two drachms 24 grains in a pound of each plant; the quantity of calcareous phosphoric salt being from one ounce six drachms 48 grains, to one drachm 12 grains.—M. Hassenfratz also observes, that the phosphoric acid is procurable from all kinds of iron; though in some it seems to proceed from that contained in the earth, and in others from the coals employed in the reduction.

The phosphoric acid is also found by Dr Marquart to be contained in the gastric juice of animals. One pound four ounces of the gastric juice of oxen gave 10 grains of a lymphatic matter, exactly like the blood in its qualities; 16 grains and six-sevenths of phosphoric acid, which with a blow-pipe was changed into a very pure and deliquescent glass of phosphorus; five grains of phosphorated lime, two grains of resin, 14 grains of sal ammoniac, 29 grains of common salt, a very small quantity of an extract whose nature was difficult to ascertain; one pound three ounces six drachms and $67\frac{1}{7}$ grains of water; so that the solid contents were only 166th part of the bulk.

In sheep, the quantity of gastric juice was about eight ounces in quantity, of a deeper and brighter green.

904
Phlogistic acid.

Acid of
Phosphorus
and its
Combina-
tions.

green than that of oxen or calves; but affording the same ingredients, though in a different proportion; though no other acid than that of phosphorus could be discovered. It was also more disposed to putrefaction. Calves furnished from four to six ounces of gastric juice, which contained very little lymph, but afforded some quantity of dry jelly, though the whole was not equal to the proper proportion of lymph. The phosphorated lime was in the usual quantity, but the disengaged phosphoric acid in a very small proportion. The lacteal acid was found in great quantity; to which, along with that of phosphorus, our author supposes the property of curdling the milk in the animal's stomach to be owing.

The phosphoric acid has also been found in very large quantity in the calcareous stones of Andalusia; and Mr Klaproth has found the same combined with calcareous earth in a kind of beryl, crystallized in hexahedral prisms, called by M. Verner *apatit*.—Formerly the best method of obtaining it was from urine, where it is contained in very considerable quantity in combination with the volatile alkali, and forming a salt called the *microcosmic*, or *essential salt of urine*.

905
Microcos-
mic salt,
how procu-
red.

To procure this, a large quantity of urine is to be evaporated to the consistence of a thin syrup; which, being set in a cold place, will yield, in three or four weeks, foul brown-coloured crystals, which are the microcosmic salt, mixed with the marine, and other salts of urine. These crystals are to be dissolved in hot water; the solution filtered whilst it continues hot, and set to crystallize again; and the solution, filtration, and crystallization, repeated till the salt becomes pure and white. In all the crystallizations the microcosmic salt shoots first, and is easily distinguished and separated from the others. If the urine which remains after the first crystallization be further evaporated, and again set in the cold, it will yield more crystals; but browner and more impure than the former; and therefore requiring to be purified by themselves. From 20 gallons of urine may be obtained four ounces of pure salt; a considerable part being still left in the residuum.

In these operations the heat ought to be gentle, and the vessels either of glass or compact stone-ware. Urine being evaporated in a copper vessel, afforded only a green solution of that metal.

906
Mr Mar-
graaff's ex-
periments.

Concerning the nature of the microcosmic salt obtained by the above process, Mr Margraaf gives the following account in the Berlin memoirs for 1746.

“Sixteen ounces of the salt, distilled in a glass retort, in a heat gradually raised, gave over eight ounces of a volatile urinous spirit, resembling that made from sal ammoniac by quicklime. The residuum was a porous brittle mass, weighing eight ounces. This, urged with a stronger fire in a crucible, bubbled and frothed much, and at length sunk down into the appearance of glass, without seeming to suffer any further diminution of its weight in the most vehement heat.

The vitreous matter dissolved in twice or thrice its quantity of water, into a clear, transparent, acid liquor, somewhat thick, not ill resembling in consistence concentrated oil of vitriol. This liquor totally corroded zinc into a white powder, which, being diluted

with water, appeared in great part to dissolve, fixed alkalies occasioning a plentiful precipitation. It acted powerfully upon iron, with some effervescence; and changed the metal into a kind of muddy substance inclining to bluish, in part soluble in water like the preceding. It dissolved likewise a portion of regulus of antimony, and extracted a red tincture from cobalt. On lead and tin it had very little action. Copper it corroded but slightly. On bismuth, silver, and gold, it had no effect at all, either by strong digestion, or a boiling heat. Nor did the adding of a considerable portion of nitrous acid enable it to act upon gold.

“The vitreous salt in its dry form, melted with metallic bodies with a strong fire, acts upon them more powerfully. In each of the following experiments, two drachms of the salt were taken to two scruples of the metal reduced to small parts. (1.) Gold communicated a purple colour to the vitreous salt; on weighing the metal, however, its diminution was not considerable. (2.) Silver lost four grains, or $\frac{1}{10}$; and rendered the salt yellowish, and moderately opaque. (3.) Copper lost only two grains, or $\frac{1}{20}$, though the salt was tinged of a deep green colour. It seemed as if a portion of the salt had been retained by the metal, which, after the fusion, was found to be whiter and more brittle than before. (4.) During the fusion with iron, flashes like lightning were continually thrown out; a phosphorus being generated from the combination of the acid with the inflammable principle of the iron. Great part of the mixture rises up in froth; which, when cold, appears a vitreous scoria, covered on the surface with a kind of metallic skin, which, on being rubbed, changes its green colour to a yellowish. The rest of the iron remains at the bottom of the crucible, half melted, half vitrified, and spongy. (5.) Tin lost 18 grains, or nearly one-half its weight, and rendered the salt whitish; the remaining metal being at the same time remarkably changed. It was all over leafy and brilliant, very brittle, internally like zinc. Laid on burning coals, it first began to melt, then burnt like zinc, or phosphorus. (6.) Lead lost 16 grains, and gave the same whitish colour to the scoriae that tin does. The remaining lead was in like manner inflammable, but burnt less vehemently than the tin; from which it differed also in retaining its malleability. (7.) Mercury precipitated from aquafortis, and well edulcorated, being treated with the salt in a glass retort, with a fire raised to the utmost, only 12 grains of mercury sublimed; 28 remaining united with the acid, in a whitish, semi-opaque mass. A solution of this mixed in distilled water, deposited a quantity of a yellowish powder; which, by distillation in a glass retort, was in great part revived into running mercury. A part also remained dissolved in the clear liquor; for a drop let fall on polished copper instantly whitened it. (8.) Regulus of antimony melted with the vitreous salt, lost eight or nine grains, (about $\frac{1}{2}$); the regulus assumed a fine, brilliant, striated appearance; the scoriae were somewhat opaque. (9.) Bismuth lost eight grains; the scoriae were like the preceding, but the bismuth itself suffered little change. (10.) Zinc, mixed with the salt, and distilled in a glass retort, yielded a true phosphorus, which arose in a very moderate heat. The residuum was of a grey colour, a little melted at

Acid of
Phosphorus
and its
Combina-
tions.

Acid of
Phosphorus
and its
Combina-
tions.

the bottom, in weight not exceeding two drachms; so that two scruples had sublimed. This residuum, urged further in a small Hessian crucible to perfect fusion, emitted an infinity of phosphorine flashes, with a kind of detonation. The matter, grown cold, looked like the scoriae of melted glass. (11.) White arsenic, mixed with this salt, separated in the fire, greatest part of it subliming, and only as much remaining behind as increased the weight of the salt eight or nine grains. This compound appeared at first transparent; but, on being exposed to the air, became moist, and of an opaque whiteness, much resembling crystalline arsenic. (12.) Cinnabar totally sublimed; suffering no change itself, and occasioning none in the salt. Sulphur did the same. (13.) One part of the salt, mixed with ten of manganese, and melted in a close vessel, gave a semitransparent mass, some parts of which were bluish. The crucible was lined with a fine purple glazing, and the edges of the mass itself appeared of the same colour.

"The vitreous salt dissolved also, in fusion, metallic calces and earths. Chalk, with one third its weight of the salt, formed a semitransparent vitreous mass: calcined marble, with the same proportion, flowed so thin as to run all through the crucible; gypsum, likewise, ran mostly through the crucible; what remained was semitransparent. Lapis specularis ran entirely through the vessel. Spanish chalk gave a semitransparent mass, which sparkled on breaking; and fine white clay, a similar one. Saxon topaz and flint were changed into beautiful opal-coloured masses; the earth of alum into a semitransparent mass, and quicklime into an opaque white one. The mass with flints imbibed moisture from the air; the others not.

"Oil of vitriol, poured upon one-fourth its weight of this salt in a retort, raised an effervescence, acquired a brownish colour, and afterwards became turbid and white. On raising the fire, the oil of vitriol distilled, and the matter in the bottom of the retort melted. In the neck was found a little sublimate, which grew moist in the air; as did likewise the remaining salt, which was opaque and whitish. Concentrated spirit of nitre, distilled with this salt in the above proportion, came over unchanged; no sublimate appeared; the residuum looked like glass of borax. The distilled spirit did not act in the least upon gold, even by coction. Strong spirit of sea-salt being distilled in the same manner, no sensible change was made either in the spirit or the salt.

"Equal parts of the vitrified microcosmic salt and salt of tartar being urged with the strongest fire that a glass retort could bear, nothing sensible came over, nor did the mixture appear in thin fusion. Dissolved in water, filtered, and duly evaporated, it afforded, very difficultly, oblong crystals, somewhat alkaline; the quantity of alkali having been more than enough to saturate the acid. A whitish matter remained on the filter, amounting to seven or eight grains, from two drachms of the mixture; this, after being washed and dried, melted before a blow-pipe, as did likewise the crystals.

"This salt seems to extricate, in part, the acids of vitriolated tartar, nitre, and sea-salt. (1.) On distilling a mixture of it with an equal quantity of vitriolated tartar, there came over some ponderous acid drops,

which, saturated with fixed alkali, formed a neutral salt greatly resembling the vitriolated tartar. The residuum readily dissolved in water, and difficultly crystallized. (2.) Nitre, treated with the same proportion of the salt, began to emit red vapours. The residuum was of a peach-blossom colour, appeared to have melted less perfectly than the preceding, and dissolved more difficultly in water. The solution deposited a little earthy matter; and, on being slowly evaporated, shot into crystals, which did not deflagrate in the fire. (3.) Sea-salt, distilled in the same manner, manifestly parted with its acid; the residuum was whitish, readily dissolved in water, and afforded some cubical crystals. (4.) Sal ammoniac suffered no change. (5.) Borax, with an equal quantity of vitreous salt, run all through the crucibles.

"Solutions of this salt precipitated the earthy part of lime-water, of solution of alum, of flint dissolved in fixed alkali, and the combination of marine acid with chalk or quicklime. The precipitate from this last liquor is tenacious like glue, and does not dissolve even in boiling water; exposed to a strong fire, it froths prodigiously, and at last melts into a thick scoria.

"Solutions of this salt precipitate also sundry metallic solutions; as butter of antimony, solutions of silver, copper, lead, iron, mercury, and bismuth, in the nitrous acid; and of tin in aqua regis. The precipitate of iron from spirit of salt is a tenacious mass; that of silver from aquafortis, sometimes a white powder, sometimes tenacious. Copper from aquafortis is sometimes thrown down in form of a white powder, and sometimes in that of a green oil, according to the proportions and diluteness of the liquor. Silver is not precipitated at all by this acid from its solution in vinegar, nor gold from aqua regis.

"An ounce of the vitreous salt, well mixed with half an ounce of soot, and committed to distillation, yielded a drachm of fine phosphorus. The black residuum, being elixated with boiling water, and the liquor passed through a filter, there remained upon the filter eight scruples of a black matter; and, on evaporating and crystallizing the liquor, about seven drachms were obtained of oblong crystals, which did not deliquesce in a moist air, but became powdery in a warm one. These crystals, treated afresh with inflammable matter, yielded no phosphorus. Before a blow-pipe they melted into a transparent globular mass, which, on cooling, became turbid and opaque. Dissolved in water, they precipitated solutions of silver, mercury, copper, and of chalk; though they did not act upon the latter so powerfully, nor produce with it a gluey mass, as before they had been deprived of their phosphorine acid."

Mr Wiegand informs us, that the phosphoric acid exhibits less affinity with calcareous earth, in the moist way, than the vitriolic; though it cannot be separated from the ultimate residuum of the calcareous earth by that acid. It expels, however, all the liquid acids from their basis in the dry way. It precipitates iron from a solution in vitriolic acid, of a perfectly white colour. For the uses of this acid as a flux, see the article *Blow-pipe*.

§ 10. Of the Acid of Ants.

THE acid may be obtained from these insects either by

ties.

by distillation, or simple infusion in water. From twenty-four ounces of ants, Neumann obtained eleven ounces and an half of acid as strong as good vinegar, by distillation in balneo marie. Of this acid, Mr Margraaff gives the following account in the Berlin Memoirs for 1749.

"The acid of ants effervesces with alkaline salts, both fixed and volatile. With volatile alkalies it forms a neutral liquor, which, like that composed of the same alkalies and vinegar, yields no concrete salt on distillation. With fixed alkalies it concretes, upon proper exhalation, into oblong crystals, which deliquesce in the air. The crystals, or the saturated neutral liquor uncrystallized, on being distilled with a fire increased till the retort began to melt, yielded a liquor scarce sensibly acid, and afterwards a small quantity of an urinous and partly ammoniacal liquor. The remaining black matter, dissolved in distilled water, filtered and evaporated, shot into large crystals which did not deliquesce in the air, though they were in taste strongly alkaline, effervesced with acids, and had all the other properties by which fixed alkalies are distinguished.

"This acid dissolves, with great effervescence, coral, chalk, and quicklime; and concretes with them all into crystals which do not deliquesce in the air.

"It does not precipitate silver, lead, or mercury, from the nitrous acid; nor quicklime from the marine. Hence it appears to have no analogy to the marine or vitriolic acids; the first of which constantly precipitates the metallic solutions, and the other the earthy.

"It does not act upon filings of silver; but (like vegetable acids), it totally dissolves, by the assistance of heat, the calx of silver precipitated from aquafortis by salt of tartar.

"It does not dissolve calces of mercury (as vegetable acids do); but revives them into running quicksilver.

"It acts very weakly upon filings of copper; but perfectly dissolves copper that has been calcined. The solution yields beautiful compact green crystals.

"It dissolves iron-filings with violence; the solution, duly evaporated, shoots into crystals more readily than that made in distilled vinegar. It scarcely acts at all upon filings of tin.

"It does not, according to Mr Margraaff, corrode filings of lead; but dissolves, by the assistance of heat, the red calx of lead. The solution crystallizes into a saccharum saturni. In Mr Ray's philosophical letters, it is said, that lead put into the acid spirit, or fair water, together with the animals themselves, makes a good *saccharum saturni*; and that this saccharum, on being distilled, will afford the same acid spirit again, which the saccharum saturni made with vinegar will not do, but returns an inflammable oil with water, but nothing that is acid: and saccharum saturni made with spirit of verdigris doth the same in this respect with spirit of pissmires.

"It dissolves zinc with vehemence, and shoots, upon due evaporation, into inelegant crystals, not at all like those produced with distilled vinegar. On bismuth, or regulus of antimony, it has little effect, either when calcined or in their metalline state."

§ 11. Of the Acid of AMBER.

Acid of
Amber and
its Combi-
nations.

909

Mr Pott's
experi-
ments.

THE nature of this acid is as yet but little known, and Mr Pott is the only chemist who seems to have examined it with accuracy. We shall therefore give an abstract of the principal observations and experiments he has made on this salt.

"Salt of amber requires a large quantity of water for its solution. In the first crystallization (being much impregnated with the oil, which rises from the amber along with it), it shoots into spongy flakes, in colour resembling brown sugar-candy; the crystals which succeed prove darker and darker coloured. On repeating the depuration, the crystals appear at top of a clear yellow or whitish colour, in form of long needles or feathers; at bottom, darker, and more irregular, as are likewise the crystals which shoot afterwards. The crystals neither liquefy nor become powdery in the air: rubbed, they emit a pungent smell like that of radishes, especially if warmed a little; their taste is acid, not in the least corrosive, but with a kind of oily pungency.

"This salt, kept in the heat of boiling water, loses nothing of its weight, and suffers no alteration. In a great heat it melts like oil; after which a little oily acid arises, then oily stræ appear in the lower part of the retort, and the salt sublimes into the neck, partly in the form of a dark yellow butter, and partly in that of feathers, a black coaly matter remaining at bottom; so that, by this process, a part of the salt is destroyed.

"Oil of turpentine has no action on this salt. Highly rectified spirit of wine gains from it a yellow colour in the cold; and, on the application of heat, dissolves a considerable quantity, but deposits great part of it on cooling. The salt thus deposited is somewhat whiter than before, but still continues sensibly yellow. The dulcified spirit of sal ammoniac dissolves it readily, without effervescence, into a yellow liquor; if the salt was foul, the solution proves of a red colour; on burning of the vinous spirit, a neutral liquor remains.

"A solution of salt of amber in water, saturated with a pure alkaline lixivium, yielded, on inspissation, a saline matter, which would not crystallize, and which, when exsiccated by heat, deliquesced in the air, leaving a considerable proportion of an earthy, unctuous matter. Being again gently inspissated, it left a brownish salt, very soluble, weighing one half more than the salt of amber employed. This salt effervesced with the vitriolic and nitrous acids: the vapour, which exhaled, was not acid, but oily and sulphureous. On repeating the experiment, and fully saturating the alkali with the salt of amber, the neutral salt made no effervescence with these acids. This salt did not perfectly melt before a blow-pipe; continued in the fire for some time, it effervesced with aquafortis. In distillation it yielded a bitter, oily, alkalescent spirit, much resembling the spirit of tartar; and towards the end, an empyreumatic oil. The residuum elixated, yielded the alkaline salt again of a brown colour.

"Salt of amber effervesces strongly with volatile alkalies; and, on saturation, forms with them an oily

ammoniacal liquor, which, in distillation, totally arises in a fluid form, except that a small portion of a penetrating, oily, saline matter, concretes towards the end.

"On distilling salt of amber with an equal quantity of common sal ammoniac, a marine acid spirit came over, of a strong smell, and a brown colour: afterwards, a little white sal ammoniac sublimed; at length arose suddenly a large quantity of a fuliginous or bituminous matter, leaving behind a small portion of a like shining black substance. The coaly matter was considerably more in quantity than the salt of amber employed. On treating it with nitre, red vapours arose, and the mixture detonated with violence. A mixture of it with borax, frothed and swelled up much more than borax by itself; and, on raising the fire, yielded only some oily drops; the acid being destroyed by this salt, as by fixed alkalies and quicklime.

"Spirit of sea salt, poured upon one-fourth its weight of salt of amber, made scarce any solution in the cold: on the application of heat, nearly the whole coagulated into the consistence of a jelly. In distillation, the spirit of salt arose first; then almost the whole of the salt of amber, partly like firm butter, partly like long striated plumous alum, very pure, and of a fine white colour, its oily matter being changed into a coal at the bottom. The salt, thus purified, makes no precipitation in the solution of silver, and consequently retains nothing of the marine acid; nor does it precipitate solution of quicklime made in spirit of salt, and consequently contains nothing vitriolic. If any of the mineral acids was contained in this salt, it could not here escape discovery; the oil, which in the rough salt is supposed to conceal the acid, being in this process separated.

"Aqua fortis being poured upon one-fourth its weight of salt of amber, extracted a yellowish colour from it in the cold, but dissolved little: on the application of heat, the whole dissolves into a clear liquor, without any coagulation: if the salt is very oily, the solution proves red. In distillation, the greatest part arises in a liquid form, with only a very small quantity of concrete salt. The spirit does not act upon gold, but dissolves silver, and quicksilver, as at first; a proof that it has received no marine acid from the salt of amber.

"Oil of vitriol being added to twice its weight of salt of amber diluted with a little water, a moderate fire elevated an acidulous liquor, which appeared to proceed from the salt of amber; for its making no change in solution of fixed sal ammoniac, showed it not to be vitriolic. On continuing the distillation by a stronger fire, greatest part of the salt arises undestroyed, and the oil of vitriol along with it; a black, light, porous earth remaining.

"Equal parts of quicklime and salt of amber gave over in distillation only an acidulous phlegm; the residuum, elixated with water, yielded a solution of the lime in the acid of amber, resembling a solution of the same earth in vegetable acids, precipitable by alkaline salts, and by the vitriolic acid. Lime, added to a watery solution of salt of amber, dissolves with some effervescence; after which, the whole coagulates into

the consistence of a jelly: this, diluted with water, proves similar to the foregoing solution.

"Solution of salt of amber makes no precipitation in solutions of silver or quicksilver. It dissolves zinc, as all acids do: fixed alkalies precipitate the zinc: the volatile do not; and when a sufficient quantity of the volatile has been added, the fixed make no precipitation. It acts exceedingly slowly and difficultly upon copper; but corrodes calcined copper in a shorter time. It soon corrodes iron, by coction, into a crocus, and dissolves a part into a liquid form: the solution has little colour; but alkaline salts readily discover that it holds iron, by rendering it turbid and whitish, and throwing down a considerable quantity of a greenish calx."

§ 12. Of the Acid of ARSENIC.

Mr Scheele first perceived, from some experiments on manganese, that arsenic contained phlogiston: from whence he was led to an analysis of this substance, which produced an acid of a very singular kind; by uniting of which with phlogiston in certain proportions, either white arsenic or its regulus may be composed at pleasure.

White arsenic may be decomposed in two ways. 1. Put two ounces of it reduced to fine powder in a glass mortar into a retort of the same material; pour upon it seven ounces of pure muriatic acid, whose specific gravity is to that of water as 10 to 8; and lute on a receiver. The arsenic is quickly dissolved in a boiling heat, which must be brought on as quickly as possible. After the solution is accomplished, while the liquor is still warm, three ounces and a half of nitrous acid, of the same specific gravity with the muriatic above-mentioned, is to be added, and the liquid which had already gone over into the receiver poured back. The receiver is then to be put on again, but not luted; the mixture soon begins to effervesce, and red vapours go over into the receiver. The distillation is to be continued till these vapours cease; when an ounce of finely powdered arsenic is again to be added, the receiver applied as before, and a gentle ebullition continued until the second quantity of arsenic be dissolved. An ounce and an half of nitrous acid is then to be added, and the mixture distilled to dryness, increasing the fire towards the end, so as to make the retort red hot. The acid which comes over into the receiver may serve again several times. The white mass which remains in the retort is the dry acid of arsenic. It may be reduced to a liquid form by pouring upon it, in coarse powder, twice its weight of distilled water, and boiling for a few minutes, pouring back the liquor which comes over, and afterwards filtering the solution through blotting paper, which has been previously washed in hot water.

In this process the nitrous acid attacks the phlogiston of the arsenic, is volatilized in consequence of its union with it, and leaves the more fixed but less powerful acid of arsenic behind. The nitrous acid would alone be sufficient for this purpose, could it accurately come into contact with the particles of arsenic; but this cannot be done without solution, and the nitrous acid is capable of dissolving arsenic only in pro-

proportion to the water it contains. Too great a quantity would therefore be required were this acid to be used by itself; but by the use of muriatic acid for the solution, a smaller quantity of spirit of nitre is admitted to intimate contact with all the arsenical particles, and has an opportunity of depriving them of their phlogiston. Aqua regia might be poured upon the arsenic at once; but the great effervescence it excites would throw the mineral up to the top in such a manner that the menstruum could not act upon it. By the operation of dephlogistication, arsenic loses a fifth part, which is supposed to be pure phlogiston.

The other method of decomposing arsenic is, by means of the dephlogisticated spirit of salt. For this purpose, take one part of powdered manganese, and mix it with three of the muriatic acid above-mentioned. Put it into a retort, of which it may fill one-fourth; a receiver containing one-fourth of powdered arsenic, with one-eighth of distilled water, is to be luted on, and the retort put into a sand-bath. The dephlogisticated muriatic acid, going over into the receiver, is instantly absorbed by the arsenic; which some hours afterwards will be dissolved, and two different liquid strata, which cannot be mixed together, will be perceived in the receiver. This solution is now to be put into a clean glass retort, and distilled to dryness; increasing the fire at last to such a degree as to make the whole red hot: and in this process also two different liquids pass over into the receiver which do not unite together.

Here the manganese attracts the phlogiston of the muriatic acid; and as this dephlogisticated acid has a very strong attraction for phlogiston, it deprives the arsenic of its phlogiston, and thus recomposes the ordinary phlogisticated muriatic acid. This portion of recomposed acid dissolves part of the arsenic, forming with it what is called *butter of arsenic*. The other part of the arsenic which has been decomposed, dissolves in the water, and forms a liquid specifically lighter than the butter, and therefore swims above it. On rectifying the two liquids, the undecomposed portion of the arsenic arises along with the muriatic acid, and goes over into the receiver in form of an heavy oil, while the acid of arsenic remains behind in the retort. The acid obtained in this way is precisely the same with the former, and one would hardly believe that it is an acid, because it has no acid taste; but after some days it grows moist in the air, and at last deliquesces, assuming the appearance of oil of vitriol. As the deliquescence, however, is very slow, it is proper to dissolve it in a certain quantity of water, when a small quantity of white powder remains undissolved, after preparing it by the first process, which is siliceous earth derived from the retort. This ought to be carefully separated from the acid by filtration; and in order to prevent the glue of the blotting-paper from mixing with the acid, it was directed to wash the filter with hot water previous to the operation.

The first experiment M. Scheele tried on this acid after he had obtained it, was to discover if it was as noxious to animals as when combined with phlogiston. Having mixed a little with honey, the flies that eat of it died in an hour; and eight grains reduced a cat to the point of death in two hours. Some milk, how-

ever, being then given to the animal, it vomited violently, and ran away.

2. An ounce of dry acid of arsenic, heated in a small phial to near the point of ignition, melts into a clear liquid, which congeals when cold; but if the heat be increased till the vessel begins to melt, the acid begins to boil, resumes its phlogiston, and arsenic sublimes in greater quantity as the heat is longer continued. After subjecting the acid to this violent heat in a retort for an hour, the vessel melted, and the acid had risen up as high as the neck.

3. In a crucible the arsenic attracts phlogiston in greater quantity, and is entirely dissipated in arsenical vapours; a little clear and difficultly fusible glass, consisting of clay and the acid of arsenic, remaining in the crucible.

3. With powder of charcoal the arsenical acid undergoes no change; but if the mixture be put into a retort, the moisture all driven off, a receiver then luted on, and the heat increased till the bottom of the retort becomes red hot, the whole mass takes fire with violence; all the acid is reduced, and sublimed into the neck of the retort; a shining regulus is obtained mixed with a little arsenic and charcoal dust. A few drops of water are found in the receiver, but they do not contain a particle of acid.

4. The arsenical acid, after some days digestion with oil of turpentine, unctuous oil, and sugar, becomes black and thick. If some muriatic acid be distilled from this, a little nitrous acid added, and the distillation repeated, some acid of arsenic is left behind. Spirit of wine undergoes no change either by digestion or distillation with arsenical acid.

5. Six parts of acid digested with one of sulphur suffer no change; but when the mixture is evaporated to dryness, and then subjected to distillation in a glass retort, the two unite with great violence at that degree of heat in which sulphur melts; and the whole mass rises almost in the same instant, in form of a red sublimate; a little sulphureous acid in the mean time going over into the receiver.

6. Acid of arsenic, saturated with vegetable fixed alkali, forms a deliquescent salt which does not crystallize, but turns syrup of violets green, though it produces no change on the tincture of lacmus. On the addition of a little more acid, however, when it reddens lacmus, but makes no alteration on the syrup of violets, the liquor will afford fine crystals like Mr Macquer's neutral salt of arsenic. On keeping this salt for an hour in fusion in a crucible covered with another luted upon it, the inside of the vessel was found covered with a white glazing, and a salt remained, which was still the same arsenicated salt with excess of acid.

7. On distilling this salt in a retort with an eighth-part of charcoal-dust, it began to boil very violently as soon as the retort became red-hot, and a very fine regulus of arsenic sublimed. The black residuum contained the alkali entirely separated from the arsenical acid.

8. With mineral alkali the acid of arsenic forms crystals when perfectly neutralized, but not if added to excess. In that case, the mass becomes deliquescent like the former when neutral.

9. With volatile alkali a salt much resembling the

two former is produced. It does not change lacmus, but turns the syrup of violets green. A gentle heat drives off part of its volatile alkali, and leaves the remainder supersaturated with acid; in which case it shoots into long radiated and deliquescent crystals. These, urged by a stronger heat, part with the whole of their alkali, which is partly decomposed; some arsenic is formed by the union of the phlogiston of the alkali with part of the arsenical acid; the remainder of which assumes a milky colour, and lies in the bottom of the retort.

10. Acid of arsenic distilled with vitriolated tartar expels the vitriolic acid in a violent heat, which comes over in a concentrated but sulphureous state, leaving the arsenical salt formed of the acid and alkali united. With Glauber's salt the vitriolic acid also rises, and with less heat than when vitriolated tartar is made use of.

11. One part of nitre distilled with three of acid of arsenic, yielded a spirit of nitre, together with the neutral arsenical salt already mentioned.

12. One part of common salt with three of arsenical acid, yielded some smoking spirit of salt. The residuum dissolved in water gave crystals of common salt, and a thick magnum, which would not crystallize till the superfluous arsenical acid was taken away by adding powdered chalk, when it yielded crystals similar to those produced by the acid and pure alkali.

13. With sal ammoniac the product was first fuming muriatic acid, then volatile alkali in a liquid state, after that arsenic, and lastly part of the arsenical acid remained in the retort.

14. Spathum ponderosum, and gypsum, both parted with their acids, which were become sulphureous. The former did not yield its acid till the retort began to melt.

15. One part of fluor mineral was mixed with four of acid of arsenic, and distilled into a receiver having a little water in it. When the retort grew red-hot, first a yellow and then a red substance sublimed. Some sulphureous acid, but none of the acid of fluor, went over. A grey-coloured residuum was left in the retort; which being divided into two parts, one was mixed with charcoal-powder and distilled with a strong fire, without the production of either arsenic or regulus; the other was mixed with four parts of acid of arsenic, and subjected to a second distillation. When the mass grew dry, a little yellow sal-ammoniac was sublimed, and the water was covered with a crust of filiceous earth, as in the usual distillations of that mineral.

16. Arsenical acid precipitates lime-water, by uniting with the calcareous earth dissolved in it. By the addition of more acid, the precipitate is dissolved, and the liquor yields small crystals, which let fall a selenite on the addition of vitriolic acid.

17. On the addition of powdered chalk to arsenical acid diluted with water, the earth is at first dissolved, but by adding more chalk the whole is coagulated into small crystals.

18. Magnesia dissolves in the arsenical acid, and the solution coagulates when it comes to the point of saturation. On dissolving the coagulum in a larger quantity of water, it becomes gelatinous by evaporation; and if the jelly be lixiviated with water, filtered, and evaporated, a viscid mass remains, which refuses to crystallize.

N° 73.

19. Earth of alum precipitated by alkali of tartar is easily soluble in arsenical acid, and coagulates as soon as it arrives at the point of saturation. Evaporated to dryness, mixed with some charcoal powder, and then subjected to strong distillation, a little yellow sublimate rises into the neck of the retort, as likewise some shining regulus, while a volatile sulphureous acid passes over into the receiver. The residuum dissolves with difficulty in the vitriolic acid, though some crystals of alum will form in the space of two months.

20. Four parts of arsenical acid mixed with one of powdered white clay, did not dissolve any part by digestion for a fortnight. By distillation in a retort till the vessel began to melt, it was converted into a thick flux, and a little arsenic sublimed. By mixing the residuum with a little powdered charcoal, a shining regulus was sublimed.

21. Terra ponderosa dissolves readily in the acid of arsenic, but precipitates again as soon as it has attained the point of saturation. The solution is precipitated by acid of vitriol, and forms regenerated ponderous spar.

22. Gold is not acted upon by acid of arsenic, either by digestion or otherwise; nor is its solution precipitated, though the retorts used in the operation were stained with red and yellow spots, which could not be taken off; nor is its action increased by mixture with muriatic or with nitrous acid.

23. Pura platina is not acted upon. Its solution is not precipitated by the pure arsenical acid, but readily by the arsenical salts. The precipitate is yellow, and dissolves in a large quantity of water, but contains no mark of arsenical acid. Addition of muriatic or of nitrous acid makes no change in its effects.

24. Pure silver is not acted upon by the arsenical acid in digestion. On augmenting the fire till the acid melted, and keeping up this degree of heat for half an hour, the metal dissolved, and on breaking the retort, a colourless glassy mass, nearly transparent, was found in it; the retort being covered with a flame-coloured glazing, which could not be separated from it. By a great degree of heat the silver was reduced without addition. Solution of silver is precipitated by pure acid of arsenic, but more effectually by the neutral arsenical salts: the precipitate is of a brown colour, and by digestion in muriatic acid is changed into luna cornea; it is also soluble in spirit of sal ammoniac prepared with quicklime. The action of the arsenical acid upon silver is considerably increased by mixing it with spirit of sea-salt; the former attacking the phlogiston of the metal, while the latter attacks its earthy basis.

25. Quicksilver is not acted upon by digestion with arsenical acid. On putting the mixture into a retort, distilling to dryness, and then increasing the fire, the mass becomes yellow, quicksilver rises into the neck of the retort, with a little arsenic, and some yellow sublimate; but though the fire was augmented till the retort began to melt, the mass could not be fused. Three drachms and an half of quicksilver were obtained out of six employed in the experiment; the arsenical acid, therefore, contained two and an half. The mass was somewhat yellow: it dissolved very readily in muriatic acid, but scarcely at all in the nitrous or vitriolic; on evaporation to dryness and distillation, some corrosive sublimate

With lead.

sublimate rose into the neck of the retort; the residuum, melted in a very strong fire, proved to be acid of arsenic. Another portion of the mass, distilled with two parts of common salt, yielded corrosive sublimate.

26. Acid of arsenic distilled with corrosive sublimate undergoes no change; but by sublimation with mercurius dulcis, a corrosive sublimate is obtained. Some have asserted, that by subliming arsenic with corrosive sublimate, a butter of arsenic is obtained; but Mr Scheele informs us that this is a mistake; and that, by distilling this mixture, he constantly obtained corrosive sublimate at first, and arsenic afterwards. With regulus of arsenic, however, a smoking butter of arsenic, mercurius dulcis, and some quicksilver, are obtained. The same thing happens with a mixture of orpiment and corrosive sublimate.

27. Arsenical acid dissolves copper by a digesting heat. The solution is of a green colour; a quantity of light blue powder is deposited, and attaches itself to the copper. This powder consists of the acid of arsenic and calcined copper. On mixing two parts of dry acid of arsenic, in fine powder, with one of filings of copper, and distilling the mixture, some arsenic rose into the neck, and the mass melted and turned blue. On boiling it with water, the solution was similar to one made directly from acid of arsenic and copper. A little copper remained in the bottom of the retort, which was tinged with brown, red, and yellow spots, insoluble in any menstruum. The solutions of this metal are not precipitated by arsenical acid, but the acetous solution is. Neutral arsenical salts throw down a blue precipitate, which by exposure to a strong fire, turns brown and covers the inside of the containing vessel with a yellow enamel. On mixing the scoria in fine powder with a little lamp-black, some fine regulus of arsenic sublimed, and the copper in the residuum was reduced.

28. With iron the acid of arsenic forms a gelatinous solution, which by exposure to the air grows so thick that in two hours time it will not flow out at the mouth of a phial. With alkali of tartar a whitish green powder is thrown down; which beingedulcorated and distilled in a glass retort, yields some arsenic, and leaves a red ochre behind. On distilling four parts of arsenical acid with one of iron filings, the mass effervesced strongly towards the end; and when it became dry, took fire in the retort upon increasing the heat, when both arsenic and regulus of arsenic were sublimed. The residuum was black, friable, and contained but little acid of arsenic; the retort was covered with yellowish brown spots. Solutions of iron in mineral acids are not precipitated by acid of arsenic, but the acetous solution lets fall a dark brown powder. All the solutions are precipitated by the arsenical neutral salts, the precipitates by a strong fire, converted into black scoriae; which mixed with powdered charcoal, and calcined, yield copious vapours of arsenic, and are afterwards attracted by the magnet.

29. Lead digested with arsenical acid turns black at first, but in a few days is surrounded with a light greyish powder, containing some arsenic which may be separated by sublimation. On distilling one part of shavings of lead with two of dry acid of arsenic,

the lead was dissolved, the mass flowed clear, and a little arsenic rose into the neck of the retort. A milky glass was found in the bottom, which by boiling in distilled water, let fall a quantity of white powder, the superfluous acid being dissolved in the water; theedulcorated powder yielded regulus of arsenic by distillation with charcoal. Solutions of lead in nitrous and muriatic acids are precipitated by arsenical acid.

30. Tin digested with acid of arsenic becomes first black, then is covered with a white powder, and afterwards becomes gelatinous. One part of tin filings distilled with two of acid of arsenic, took fire as soon as the retort became red-hot, and immediately after both arsenic and a little regulus were sublimed. The tin was dissolved into a limpid liquor, which became milky when cold.—By washing in water, a quantity of white powder was separated, insoluble in any acid, and containing very little of that of arsenic.

31. Arsenical acid dissolves zinc with effervescence. The metal grows black, and the transparency of the acid is destroyed by a quantity of black powder. This powderedulcorated, dried, and put on an iron plate heated nearly red hot, emits a blue flame and white arsenical smoke in the dark, leaving behind a white powder; thus manifesting itself to be mostly regulus of arsenic. One part of filings of zinc distilled with two of acid of arsenic, took fire in the retort with a very bright flame, and burst the vessel with an explosion. Some regulus of arsenic and flowers of zinc were found in the neck.

32. Bismuth digested with acid of arsenic is covered with a white powder; water precipitates the solution, and the precipitate consists of calcined bismuth and acid of arsenic. On distilling one part of bismuth with three of arsenical acid, the mass melted, the metal was calcined, but remained undissolved in the bottom of the vessel; a little arsenic rose into the neck; and after the retort became cool, water was poured on the residuum, which dissolved the acid, but the calx of bismuth remained unchanged. Solution of this femimetal in the acid of nitre was precipitated by arsenical acid. This precipitate, as well as the calx, are very difficult of fusion, but on adding a little powdered charcoal, the mixture instantly melts, the arsenic goes off in vapours, and the bismuth is reduced.

33. With regulus of antimony a quantity of white powder is produced by digestion, and the clear solution is likewise precipitated by dropping it into pure water. This powder is soluble only by muriatic acid, and may be precipitated again by the addition of water. One part of regulus of antimony distilled with three parts of arsenical acid, took fire as soon as the mass melted, and regulus of arsenic with a red matter were sublimed; a little volatile sulphureous acid came over into the receiver. On boiling the residuum in water, the acid was dissolved, a white shining powder remained behind, which on being mixed with charcoal powder and distilled, an ebullition took place, some regulus of arsenic rose into the neck of the retort, and the antimony was reduced. Butter of antimony was not precipitated by the pure acid, but very readily by the arsenical salts. Acetous and tartareous solutions of glass of antimony are precipitated by arsenical acid.

Acid of Arsenic and its Combinations

954
With cobalt.

34. Cobalt is partially dissolved, and the solution assumes a rose-colour; on putting the whole mass into a retort, distilling off the liquid, and then augmenting the fire, the mass melted, and a little arsenic was sublimed. The residuum when cold had a semi-transparent violet colour. On pouring water upon it, and putting it on hot sand, the acid was dissolved, the violet colour disappeared, and the solution assumed a dark-red colour. The bottom of the retort had a blue tinge, which could not be taken off. Solutions of cobalt in mineral acids are readily precipitated by the arsenical neutral salts. The precipitate is of a rose-colour, but melts with difficulty into a dark blue scoria.

955
With nickel.

35. Nickel, with acid of arsenic, assumes a dark green colour, and lets fall a green powder containing arsenic in substance, which may be separated from it by a gentle heat. One part of nickel distilled with two of dry arsenical acid, melted with some appearance of inflammation, yielding some arsenic at the same time. The mass was yellow, with a number of grey elevated streaks upon it, which appeared like vegetation, and were formed during the distillation. On boiling the yellow mass in water, the acid was dissolved, leaving a yellow powder behind; which, when treated with charcoal-powder, yielded regulus of arsenic, but was not reduced itself. The solutions of nickel in acids are not precipitated by arsenical acid, not even that in vinegar, but the neutral arsenical salts throw down a whitish green powder.

956
With manganese.

36. Manganese in its natural state is dissolved only in small part; but when phlogisticated it dissolves readily and totally; though, whenever the acid arrives at the point of saturation, the solution coagulates into small crystals.

957
With regulus of arsenic.

37. Regulus of arsenic digested with its own acid soon becomes covered with a white powder, which is arsenic in substance. On distilling one part of the regulus with two of the acid, the former sublimed, and the latter melted. If small pieces of regulus of arsenic be gradually added to the acid of arsenic in fusion, an inflammation takes place, and arsenic is sublimed.

2d 957
Strange phenomenon of arsenic with terra foliata tartari.

On distilling a mixture of equal parts of terra foliata tartari and arsenic, a limpid liquor like water first came over, smelling strongly of garlic; on changing the receiver, a liquor of a brownish red colour was collected, which filled the receiver with a thick cloud, emitting an intolerable smell of arsenic. On pouring this upon a filter, hardly a few drops had passed when a very thick stinking smoke suddenly arose as high as the ceiling of the room; an ebullition ensued towards the edge of the filtering-paper, and a fine rose-coloured flame broke out, that lasted for some moments.

§ 13. Of the Acid of MOLYBDÆNA.

958
How to reduce molybdæna to powder.

WE owe this, as well as the succeeding acids, to the industry of the late Mr Scheele. The substance from which he extracted it is named by Cronstedt *molybdæna membranacea nitens*.—As this substance is of a flaky nature, and incapable of pulverization by itself, our author mixed some pieces of vitriolated tartar along with it in a glass mortar; by the attrition of which it was at last reduced to a fine powder, and which was afterwards freed from the vitriolated tar-

tar by washing with hot water. He then treated this powder with all the known acids, but found none of them to have any effect upon it excepting those of arsenic and nitre. No sensible effect was perceived from the acid of arsenic until the water was evaporated; after which, by increasing the fire, a little yellow orpiment was sublimed in the neck of the retort, and some sulphureous acid passed over into the receiver. On pouring two parts of concentrated nitrous acid upon one part of powdered molybdæna, the mixture was scarce warm in the retort, when it passed all together into the recipient with great heat, and in the form of dark red vapours. Had the quantity been larger, he had no doubt that it would have taken fire; for which reason the experiment was repeated with diluted nitrous acid. Six ounces of diluted nitrous acid being poured on an ounce and a half of powdered molybdæna, no effect was perceptible till the liquor began to boil; after which a great number of red elastic vapours began to appear, and the mixture swelled considerably. The distillation being continued to dryness, the residuum appeared of a grey colour; the same quantity of nitrous acid was poured on, and the process repeated, when the residuum was whiter; and on still repeating the operation a fourth and fifth time, the remaining powder became at last as white as chalk. This residuum, after beingedulcorated with hot water, was quite tasteless and insipid when dry. The limpid liquor which ran from it, being evaporated to half an ounce, first assumed a fine blue colour, and then grew thick. On being examined, it was found to contain some iron, and was otherwise chiefly acid of vitriol. The colour disappeared on diluting the acid with water.

The white powder just mentioned is the true acid of molybdæna, and may be obtained by the help of fire alone. A small piece of molybdæna exposed on a silver plate to the blow-pipe, makes a beautiful appearance, when the white vapours attach themselves to the plate in the form of small shining scales, in the direction of the flame. This white sublimate becomes blue whenever it is in contact with the blue flame; but changes to white whenever the point of the flame is directed against it. An ounce of powdered molybdæna was mixed with four ounces of purified nitre, and detonated in a crucible heated thoroughly red hot. The mass thus obtained was of a reddish colour. On dissolving it in water, the solution was clear and colourless. A small quantity of red powder fell to the bottom of the vessel; which, when dry, weighed 11 grains, and showed itself to be an iron ochre. By evaporation vitriolated tartar and nitre were obtained; but a good deal of lixivium remained, which refused to crystallize, though no mark of superfluous alkali remained. It was then mixed with some water, to which diluted acid of vitriol was added, until no more precipitate fell. The white powder which precipitated weighed three drachms; but if too much acid be added, the precipitate will be redissolved, and the water itself retains a part of it in solution. A precipitate is likewise obtained by means of nitrous or muriatic acid.

The precipitate thus obtained, like those which result from the two former processes, is the true acid of molybdæna, and has the following chemical properties.

1. The

965
Properties
of the acid
obtained by
nitre.

1. The solution reddens lacmus, coagulates a solution of soap, and precipitates hepar sulphuris. 2. If this solution be boiled with the filings of any of the imperfect metals, it assumes a bluish colour. 3. By the addition of a little alkali of tartar, the earth becomes soluble in greater quantity in water; and after evaporation shoots into small confused crystals. 4. Under the blow-pipe this earth is soon absorbed by charcoal; but when placed on a silver plate it melts, and evaporates with the same phenomena as molybdæna itself. 5. By the addition of alkali, the earth is deprived of its property of being volatilized in the fire. 6. The solution, whilst hot, shows its acid power more evidently than when cold, and tinges lacmus of a deeper colour. It effervesces with chalk, with magnesia, and with earth of alum; with all of which it forms salts very difficult of solution in water. 7. It precipitates, from the nitrous acid, silver, quicksilver, and lead, as also lead dissolved in marine acid. These precipitates are reduced on burning charcoal, and the melted metal runs into the pores. Corrosive sublimate is not precipitated; neither are the solutions of the other metals. 8. Terra ponderosa is also precipitated from the nitrous and marine acids; and the precipitate is soluble in a large quantity of cold water. None of the solutions of the other earths are precipitated. 9. Fixed air is also expelled by this acid from the fixed and volatile alkalies, and forms with them neutral salts which precipitate all other metallic solutions. Gold, corrosive sublimate, zinc, and manganese, are precipitated in form of a white powder; iron and tin, from their solution in marine acid, of a brown colour; cobalt of a rose colour; copper of a blue; the solutions of alum and quicklime, white; and if the ammoniacal salt formed by the earth of molybdæna and volatile alkali be distilled, the earth parts with its alkali in a gentle heat, and remains in the retort in form of a grey powder. 10. Concentrated vitriolic acid dissolves a great quantity of this earth by means of heat. The solution acquires a fine blue colour; which, however, disappears on being heated, or by diluting the acid with water. In a stronger heat the acid flies off, leaving the earth unaltered behind. This solution becomes thick on cooling. 11. The nitrous acid has no effect upon the earth of molybdæna. 12. Boiled with the muriatic acid it dissolves in considerable quantity; and, on distilling the mixture to dryness, a dark-blue residuum remains. On increasing the heat, white flowers arise, with a little blue sublimate, and a smoking muriatic acid is found in the receiver. The residuum is of a grey colour. These flowers are only the earth of molybdæna volatilized by means of the muriatic acid, and therefore manifests the same properties. 13. If one part of this earth be distilled with two parts of vitriolated tartar, a little vitriolic acid passes over, at least when the heat is very strong; and the remaining earth is more soluble in water than before. 14. With two parts of nitre it expels, by means of distillation, a strong nitrous acid; the residuum dissolved in water is a neutral salt which precipitates all metallic solutions, and is similar to that formed by a direct union of the acid and fixed alkali. 15. Distilled with two parts of pure common salt, the acid is expelled in a smoking state, and white, yellow, and violet-coloured flowers arise, which become moist in the air, and when sprinkled on metals give them a blue colour. These flowers,

as has been already remarked, are only the acid of molybdæna volatilized by that of sea-salt.

The blue colour acquired by this earth on the contact of flame, also in the moist way in some cases, shows that it is capable of contracting an union with the phlogiston. To reduce this to certainty, Mr Scheele dissolved some of the earth of molybdæna in boiling water, with the addition of a little alkali. Into this solution he poured some drops of muriatic acid, and divided it into several parts, into each of which he put filings of several metals. The solutions soon acquired a bluish colour, which grew deeper and deeper; and in an hour's time, during which the bottle was now and then shaken, the liquor assumed a fine dark blue. That this colour depends on phlogiston, he infers from the following circumstances: 1. If, instead of the metals themselves, you take their calces, no blue colour is produced. 2. If there be dropped into the blue solution a few drops of acid of nitre, and the solution be then put into a warm place, the colour disappears. It is therefore no matter of surprise, that both silver and quicksilver should be attacked, since a double elective attraction takes place; the muriatic acid uniting with the metallic calx, and the earth of molybdæna with the phlogiston of the metals. Gold, however, is not attacked in this way. 3. Too great a quantity of muriatic acid produces not a blue but a yellowish colour, which at last turns brown if the mixture be digested; but on adding this solution to a solution of the earth of molybdæna, a blue colour as usual is produced. 4. Lixivium sanguinis, in which the acid prevails, throws down the earth of a brown colour, and the infusion of galls of a dark brown.

The acid of molybdæna, treated with various fluxes, and with charcoal, shows no signs of containing any metallic matter. Moistened with oil-olive, and committed to distillation in a strong fire, it did not sublime, but remained in the retort in form of a black powder; which, on being calcined in a crucible, sublimed in white flowers as usual. On inverting another crucible into the former, and luting the juncture, the earth remained unchanged and of a black colour, without any sign of fusion. This black powder did not dissolve in boiling water, nor even with alkali, which on other occasions so readily dissolves it; but when mixed with a triple quantity of salt of tartar, a great effervescence ensued; the produce was a neutral salt resembling that formed by the direct union of the acid and alkali.

The earth of molybdæna, procured by nitre, requires much less water for its solution; it does not expel the acid from vitriolated tartar; is more easily fused, and does not sublime in an open crucible. When fused with charcoal-powder, it affords a solution with water, containing a neutral salt, which precipitates all others. The reason of these differences is, that it contains a portion of alkali, though it be ever so frequently purified by solution and crystallization. That this is the case we know from the following experiments: 1. If to a solution of the nitrous earth of molybdæna we add some nitrous acid, the latter attacks the alkali, and the greatest part of the dissolved earth is precipitated. This, however, does not happen, except by long boiling. 2. The neutral salt obtained by fusion proves the same. This neutral salt is produced in the following manner. The earth which con-

Acid of
Molybdæ-
na and its
Combina-
tions.

tains only a small quantity of alkali operates as an acid, as appears from its changing the colour of lacmus to red; but the alkali prevents as much earth from entering into it as is necessary to its saturation with phlogiston; for the acid of molybdæna has a greater attraction for alkali than for phlogiston. The charcoal which remains after lixiviating the compound of acid of molybdæna and charcoal, yields vapours in an open crucible, and gives a sublimate containing the phlogisticated earth of manganese. This alkali fixes the earth in the open air; and hence we see also the reason why this earth does not expel the acid from vitriolated tartar; for its attraction for the alkali must diminish in proportion as it comes nearer the point of saturation; and as the pure earth contains no alkali, it attracts a little from the vitriolated tartar; and consequently there can appear but a slight vestige of vitriolic acid. This small quantity of acid likewise occasions its more easy solubility in water.

966
Molybdæ-
na recom-
posed by
uniting its
acid with
sulphur.

The pure acid of molybdæna recomposes that substance by being combined with sulphur. Mr Scheele having mixed some very fine powder of this earth with three parts of sulphur, and committed the mixture to distillation in a glass retort, the receiver was filled with the superfluous sulphureous vapours, which had also the fetid smell of volatile spirit of sulphur. In the retort a black powder remained, which on every chemical trial was found to be a true molybdæna; so that there is now no doubt of this substance being composed of a particular kind of acid united to sulphur.

§ 14. *Of the Acid of LAPIS PONDEROSUS, TUNGSTEN, or WOLFRAM.*

967
This sub-
stance con-
sidered as a
metallic
earth by
Mr Berg-
man.

968
Scheele's
method of
analysing
it.

THIS substance has been analysed both by Mr Scheele and Mr Bergman, though the former has the merit of discovering the acid contained in it; which the latter considers, as well as the earth of molybdæna, not as truly acid, but as metallic earths. Mr Scheele's experiments for analysing this substance were as follow: 1. On one part of finely powdered tungsten were poured two parts of concentrated acid of vitriol. By distillation the acid passed over unchanged; the residuum, which was of a bluish colour, after being boiled for a short time, and the liquor filtered off, deposited some vitriolated lime or gypsum by standing. 2. Twelve scruples of common nitrous acid, or pure aquafortis, being poured on two of finely powdered tungsten, no effervescence ensued; but on exposing the mixture to a strong digesting heat, it assumed a citron yellow colour. The acid was then poured off into another phial, and the yellow powderedulcorated with water. 3. On this yellow powder eight scruples of caustic volatile alkali were poured, and the phial exposed to heat; on which the yellow colour instantly vanished, and the powder became white. This solution was in like manner put into a separate phial, and the powderedulcorated; and as the matter was sensibly diminished by these operations, they were alternately repeated, till at length the whole was dissolved, excepting three grains, which seemed to be siliceous earth. The same effects ensued on treating this substance with muriatic acid, only the solution was of a deeper yellow colour. 4. The solutions made in the foregoing manner with nitrous acid being all mixed together, some drops of

phlogisticated alkali were added; by which about three grains of Prussian blue were precipitated. 5. The mixture was then saturated with caustic volatile alkali; but as no precipitate appeared, a solution of fixed alkali was added, which threw down two scruples and five grains of white earth of a mild calcareous kind. On adding some nitrous acid to the extracts made by volatile alkali, a white powder was precipitated, which, onedulcoration, proved to be the true acid of tungsten.

On treating tungsten with a strong heat in the dry way, the following appearances took place: 1. One part of tungsten mixed with four of alkali of tartar was melted in an iron crucible, and then poured out on an iron plate. Twelve times its weight of boiling water being then poured upon it, a white powder subsided to the bottom, which dissolved in a great measure in nitrous acid. 2. The undissolved part of the powder was tried; and being again mixed with four parts of alkali, was melted as before: and the mass being also dissolved in water, and nitrous acid poured on the residuum, only a very small portion of grey powder was left undissolved. 3. The ley being saturated with nitrous acid, grew thick by the precipitation of a white powder; which was afterwards washed with cold water and dried, and then proved to be the same acid of tungsten with that already described. The solution in nitrous acid precipitated with fixed alkali gave a white precipitate, which was found to be calcareous earth.

The properties of the acid of tungsten are, 1. Under the blow-pipe it became first of a reddish yellow colour, then brown, and at last black. It neither smoked nor gave any signs of fusion. 2. With borax it produced a blue, and with microcosmic salt, a sea-green glass. 3. Boiled with a small portion of the nitrous or marine acids, the powder becomes yellow, and with the acid of vitriol bluish. 4. On saturating a solution of the acid with fixed alkali, a neutral salt in very small crystals is obtained. 5. With volatile alkali this acid forms an ammoniacal salt shaped like the points of small pins. On distillation the alkali separates in a caustic state, the acid remaining behind in the retort in form of a dry yellow powder. On mixture with a solution of lime in spirit of nitre, a double elective attraction takes place, the acid of tungsten uniting itself with the lime, and that of nitre with the volatile alkali. 6. With magnesia the acid of tungsten forms a salt very difficult of solution. 7. It produces no change on solutions of alum or lime, but decomposes a solution of terra ponderosa in acetous acid, and the compound is totally insoluble in water. 8. It precipitates of a white colour solutions of iron, zinc, and copper, in the vitriolic acid; silver, quicksilver, and lead, in that of nitre; and lead in the acid of sea-salt. Tin combined with the same acid is thrown down of a blue colour; but corrosive sublimate and solutions of gold undergo no change. 9. On calcining the acid of tungsten in a crucible, it loses its solubility in water. 10. It turns black by calcination with inflammable matters and with sulphur, but in other respects continues unaltered. 11. Solution of hepar sulphuris is precipitated of a green colour by this acid, and the phlogisticated alkali white; the latter precipitate being soluble in water. On the addition of a few drops of muriatic acid to a solution of the acid

Acid of Lapis Ponderosus and its Combinations.

971 Differences betwixt the acids of tungsten and molybdæna.

972 Bergman's opinion concerning the acids of tungsten and molybdæna.

973 Why he supposed the acids to be metallic earths.

acid of tungsten in water, and spreading the liquor on polished iron, zinc, or even tin, it acquires a beautiful blue colour; and the same thing happens when these metals are put into the acid. 12. It differs from the acid of molybdæna in not being volatile in the fire; in having little attraction for phlogiston or sulphur; in turning lime yellow, and forming an insoluble compound with it, as well as with ponderous earth. It has also a stronger attraction for lime than the acid of molybdæna; for if a combination of lime and acid of molybdæna be digested in a solution of the ammoniacal salt formed by uniting the acid of tungsten with volatile alkali, the latter expels the former, and produces regenerated tungsten. 13. By uniting the acid of tungsten to a calcareous earth, a regenerated tungsten is constantly procured.

Mr Bergman observes, that the acid earth of tungsten is nearly allied to that of molybdæna; and both are in a state much resembling that of white arsenic. "It is well known (says he) that arsenic, in its semimetallic state, is nothing but a peculiar acid saturated with phlogiston; and that the white calx is an intermediate state between acid and metal, containing just phlogiston enough to coagulate the acid, but remaining still soluble in water, and showing signs of acidity. If a conclusion from analogy be admissible, all the other metals should consist in a combination of the same nature of the different radical acids, which with a certain quantity of phlogiston are coagulated to a dry earthy substance; and on full saturation are reduced to the state of complete metals."

The reasons which induced Mr Bergman to suppose that the acids in question are metallic earths, are as follow: 1. They both show a striking resemblance to white arsenic in form, in producing effects like acids, and in their difficult solubility in water. 2. Their specific gravity; that of arsenic being 3750, the earth of molybdæna 3460, and the acid of tungsten 3000. 3. Their precipitation with phlogisticated alkali; a property hitherto deemed peculiar to metallic calces. Arsenic also, properly dissolved in muriatic acid, gives, with the phlogisticated alkali, a precipitate soluble in water, in the same manner as the acid of tungsten. 4. From their property of tinging vitreous matters; which, as well as that of precipitating with the phlogisticated alkali, is reckoned to be a peculiar property of metals. The acid of tungsten produces by itself some effervescence with mineral alkali. With microcosmic salt it produces a globule at first of a light blue; more of the acid makes it a dark blue; but still it remains free from redness by refraction. A further addition makes it brown. Borax acquires a slight tinge of blue, and with more of the acid becomes of a yellowish brown colour; but remains transparent, provided no further addition be made. This ultimate brown colour cannot be driven off either by nitre or the point of the flame urged by a blow-pipe. Acid of molybdæna is no less powerful; for with microcosmic salt it produces a beautiful green colour: borax well saturated with it appears grey when viewed by the reflected rays, but of a dark violet by the refracted.

§ 15. Of the Acid of Milk.

It is universally known, that in the summer-time

milk grows sour and thick in a few days, and that this sourness continues for some time to increase. It is strongest after a fortnight has elapsed; after which, if the whey be filtered and evaporated to one half the quantity, a few curds will still settle to the bottom. 974 By saturating the whey with volatile alkali, a small quantity of animal earth precipitates; and the same thing takes place on the addition of lime-water. On the addition of a small quantity of acid of tartar, the latter soon becomes partially saturated with vegetable alkali, and is converted into tartar. Thus the acid of milk, besides its proper acid part, contains animal earth and vegetable alkali in a loose state, and which is attracted by the acid of tartar; besides all these, it has also a small quantity of the same alkali saturated with muriatic acid. It is no easy matter to separate these substances from one another; because the acid is not sufficiently volatile to rise in distillation by a gentle heat, nor are its principles sufficiently fixed to bear the action of a strong fire. With the one therefore it remains almost entirely in the retort, and with the other it is destroyed. Mr Scheele therefore used the following process.

He evaporated four whey till only one-eighth part remained; when the cheesy part being totally separated, he strained the acid; and in order to obtain the animal earth, saturated the liquor with lime, diluting the solution with a triple quantity of water. In order to separate the lime, he employed the acid of sugar, which has a stronger attraction than any other for lime. This earth therefore being separated, the matter was evaporated to the consistence of honey, and highly rectified spirit of wine poured upon it to dissolve the acid part; which being accomplished, the other saline substances were left by themselves: and, lastly, the acid solution being diluted with pure water, and the spirit separated by distillation, the pure acid remained in the retort. 976 Scheele's method of procuring the pure acid of milk.

The properties of the acid of milk are, 1. Evaporated to the consistence of a syrup, it yields no crystals; and when evaporated to dryness, it deliquesces. 2. By distillation it yields first water, then a weak acid like spirit of tartar; afterwards some empyreumatic oil, with more of the same acid, fixed air, and inflammable air; in the retort was left a fixed coal. 3. By saturation with fixed vegetable alkali it yields a deliquescent salt, soluble in spirit of wine. 4. A salt of a similar kind is obtained by combining it with mineral alkali. 5. With volatile alkali a deliquescent salt is produced, which by distillation yields a great deal of its alkali before the acid is destroyed by heat. 6. It forms deliquescent salts with terra ponderosa, lime, and clay; but with magnesia it forms small crystals, which, however, are again deliquescent. 7. It has no effect either by digestion or boiling on bismuth, cobalt, regulus of antimony, tin, quicksilver, or gold. However, after digestion with tin, it precipitated gold from its solution in aqua-regia, in the form of a black powder. 8. It dissolves iron and zinc, producing inflammable air during the solution. The liquor produced by the dissolution of iron was brown, and yielded no crystals; but the solution of zinc crystallizes. 9. Copper dissolved in this acid communicates to the liquor first a blue, then a green, and then a dark blue colour, without crystallizing. 10. Lead was dissolved after some

some days digestion; the solution had a sweet astringent taste, and would not crystallize. A small quantity of white matter fell to the bottom, which on examination was found to be vitriol of lead.

"From these experiments (says Mr Scheele) it appears, that the acid of milk is of a peculiar kind; and though it expels the vinegar from the acetated vegetable alkali, yet it seems destined, if I may so speak, to be vinegar; but from the want of such substances as, during fermentation, produce some spirituous matter, it seems not to be volatilized, though a portion of it indeed arrives at this point, and really becomes vinegar: for without a previous spiritous fermentation, or without brandy, there never arises any vinegar. But that the milk enters into a complete fermentation though there be no sign of brandy present, appears from the following experiment: If a bottle full of fresh milk be inverted into a vessel containing so much of the same liquor that the mouth of the bottle reaches below the surface of the latter, and if you expose this bottle to a degree of heat a little greater than our summer, you will find, in the space of 24 hours, that the milk is not only coagulated, but in part expelled out of the bottle; and that in a couple of days afterwards, the aerial acid extricated from the milk will have expelled the greater part of it. It was said above, that the acid of milk cannot be converted into vinegar, from the want of such substances as during fermentation produce brandy; which appears to be evident from this: If to a canne of milk you add five spoonfuls of good brandy, and expose the vessel, well corked, in such a manner, however, that you now and then give vent to the air developed during fermentation, you will find in a month, sooner or latter, that the whey will be changed into good vinegar, which, strained through a cloth, may be kept in bottles."

The acid of sugar of milk is considerably different from that just now described. To procure it, Mr Scheele poured 12 ounces of diluted nitrous acid on four ounces of finely powdered sugar of milk contained in a glass retort, to which a receiver was adapted. The retort was placed in a sand-bath, and as soon as the mixture acquired a certain degree of heat, it began to effervesce violently; for which reason, the retort and receiver were taken away from the fire. The mixture, however, continued to grow hotter and hotter, with a great emission of dark red vapours continually increasing, for half an hour. A considerable quantity of nitrous air and aerial acid were extricated during that time. Care must be taken, therefore, to have the retort and receiver both of a sufficient size, and not to make the luting too tight. When the effervescence had subsided, the retort was again placed in the sand bath, and the nitrous acid thus distilled off till the mass acquired a yellowish colour; on which the retort was immediately taken away from the fire. In two days time the solution seemed to have undergone no remarkable change, nor was there any appearance of crystals. Eight ounces more of the same nitrous acid were therefore added, and the whole exposed to the same degree of heat as before. When the mass grew warm, another effervescence, though weaker than the former, ensued; the yellow colour disappeared, and the nitrous acid was again abstracted, till the solution, which had been rendered

opaque by the appearance of a white powder in it, assumed a yellowish colour, on which the retort was again removed from the sand. After it was grown cool, the mass in the retort was found to be inspissated; it was redissolved in eight ounces of water, and filtered. Seven and a half drachms of white powder remained on the filter; the solution which passed through the filter was very acid. It was evaporated to the consistence of a syrup, four ounces more nitrous acid poured upon it, and the evaporation repeated in a sand heat. After the whole was cool, some small long acid crystals were found, together with a small quantity of white powder which was separated from it, and some more nitrous acid poured on the remaining mass, and on evaporation, more such crystals made their appearance. The same process was repeated several times; by which means the whole mass was at last changed into such crystals, and weighed about five drachms, showing in every respect the same phenomena produced by acid of sugar. The white powder, weighing seven and a half drachms, was the true acid of sugar of milk; and its properties are,

1. It burns in a red hot-crucible like oil, without leaving behind it any mark or ashes. 2. It dissolves in boiling water in the proportion of one of salt to 60 of the liquid. 3. One fourth part of the dissolved powder separates from the liquid on cooling, in form of very small crystals. 4. Half an ounce of the salt was dissolved in a glass vessel in 30 ounces of boiling water, and the solution filtered when cold. It had a sourish taste, reddened the tincture of lacmus, and effervesced with chalk. 5. Two drachms of the salt exposed to an open fire in a glass retort, melted, grew black, and frothed very much; a brown salt was found sublimed into the neck of the retort, which smelled like a mixture of salt of benzoin and salt of amber, eleven grains of coal remaining in the retort. The receiver contained a brown liquid without any mark of oil, smelling like the sublimed salt. It contained also some of the salt dissolved, which was separated from it by a gentle evaporation. The sublimed salt weighed 35 grains, had a sour taste, and was easily soluble in spirit of wine, but with more difficulty in water, and burned in the fire with a flame. 6. Concentrated vitriolic acid, distilled with this salt, became very black, frothed much, and decomposed the salt entirely. 7. Acid of sugar of milk, gradually added to a hot solution of alkali, occasioned an effervescence and coagulation in consequence of the formation of a vast number of crystals, which require eight times their weight of water to dissolve them, and separate again in a great measure from the liquid on cooling. The same phenomena took place with the mineral alkali, only the salt was somewhat more soluble, requiring only five times its weight of water for solution. If to a solution of it a solution of alkali of tartar be added, a number of small crystals will soon be formed at the bottom of the vessel, on account of the greater attraction of this acid with the vegetable alkali. 8. With volatile alkali it forms a kind of sal ammoniac, which, after being gently dried, has a sourish taste. By distillation, the volatile alkali is first separated, the lime-water precipitates, and the residuum yields the same products by distillation as the pure acid. 9. With all the earths, acid of sugar of milk forms insoluble salts.

nations.

salts. If a solution of ponderous earth in muriatic or nitrous acid be dropped into a solution of acid of sugar of milk, the former is instantly decomposed, and the earth falls to the bottom in combination with the acid of saccharum lactis. The same phenomena take place with solutions of lime in the nitrous and marine acids; but solution of gypsum is not decomposed. The same also takes place with solutions of magnesia in vegetable or mineral acids, and with earth of alum; all of which are decomposed by the neutral salts above mentioned. 10. The solution of this acid, by reason of the small quantity dissolvable in water, has no sensible effects on metals in their perfect state; but when they are reduced to calces, it then acts upon them, and forms salts, very little or not at all soluble in water. Silver, mercury, and lead are precipitated in form of a white powder; blue, green, and white vitriol, as well as manganese combined with acid of vitriol, are not precipitated; but all metallic solutions are precipitated by the neutral salts.

§ 16. Of the LITHISIAIC ACID, or Acid of the human Calculus.

982
Calculi all
of the same
nature.

THE calculi examined by Mr Scheele, with a view to discover their constituent parts, were, as he informs us, all of the same nature, whether flat and polished, or rough and angular. A small quantity of calculus in powder was put into a retort, and some diluted vitriolic acid poured upon it. The powder was not affected by a digesting heat; however, it was dissolved when the humidity was abstracted by distillation. After the dissipation of the acid, a black coal was left in the retort, and the vitriolic acid which had passed into the receiver was become sulphureous. The marine acid, whether diluted or concentrated, had no effect upon the calculus, not even when boiled with it. The nitrous acid diluted, or aquafortis, had some effect on the calculus, even in the cold. On the application of heat, an effervescence ensued with red vapours, and the calculus was dissolved. Repeating the experiment in a retort with lime-water, the latter was precipitated. The solution of calculus is acid, though the menstruum be boiled with a superabundant quantity of powder, so that there may remain a portion of it undissolved. It produces deep red spots on the skin in half an hour after it is applied; and if the saturated solution be a little more evaporated, it assumes of itself a blood-red colour, which, however, disappears on dropping in a single drop of nitrous acid. Terra ponderosa is not precipitated by it from the muriatic acid; nor are metallic solutions sensibly changed. With alkalies it becomes somewhat more yellow when the alkali is superabundant. The mixture, in a strong digesting heat, assumes a rose colour, and stains the skin in the same manner, without any sensation of burning. The mixture likewise precipitates metals of different colours; vitriol of iron, black; of copper, green; solution of silver, grey; corrosive sublimate, zinc, and lead, of a white colour. Lime water precipitates a white powder soluble in muriatic and nitrous acids without effervescence; and though there be an excess of precipitated powder, the solution will be acid. This white powder, therefore, is the acid of the calculus itself, the existence of which is also confirmed

by Mr Bergman's experiments. The further analysis of this is related under the article CALCULUS, below.

Flowers of
Benzoin,
&c.

§ 17. Of the FLOWERS of BENZOIN, Acid of LEMONS, with other anomalous vegetable acids, and the resemblance which the vegetable acids in general bear to one another.

It has long been known, that the resinous substance, improperly called gum benzoin, yields by sublimation with a gentle heat a quantity of fine saline matter of a most agreeable odour, and slightly acid taste, called flowers of benzoin. Another method of obtaining this substance is by lixiviating the gum with water, and crystallizing the salt. Mr Scheele, determined to try what quantity of the flowers could be obtained from the resin, found that, by sublimation, he was able to obtain from one pound of benzoin between nine and twelve drachms of flowers. By lixiviation the quantity obtained was considerably less than the former, owing to the saline particles being so much covered by the resin, that the water could not have sufficient access to dissolve them all. It was next attempted to procure all the flowers which the benzoin was capable of yielding. This was first done by boiling pounded chalk and benzoin in water, and then filtering the decoction; but no crystals appeared. On pouring some drops of vitriolic acid into the liquor, the salt of benzoin soon afterwards precipitated (for this salt, which is an acid, was united to the chalk); but the quantity of salt was no greater than that obtained by lixiviation. Alkaline ley was next tried, and the solution saturated with an acid. Thus the salt of benzoin was obtained by precipitation; but here this inconvenience was met with, that the powder of benzoin ran together during the boiling, and floated on the surface like a tenacious resin. One only method, therefore, remained to be tried, and that was to boil the benzoin with quick-lime; and as the particles of lime, by interspersing themselves betwixt those of the benzoin, would prevent their running together, and lime has likewise the property of acting upon the resinous particles, this seems to be the best method of procuring the flowers of benzoin in the greatest quantity, and also of the best quality; and thus we may obtain from 12 to 14 drachms of flowers from a pound of benzoin. Mr Scheele's receipt for preparing them after this new method, is as follows: "Pour 12 ounces of water upon four of unslaked lime, and after the ebullition is over, add eight pounds (of 12 ounces each) of water; put then a pound of finely powdered resin of benzoin into a tinned pan, pour upon it first about six ounces of the lime-water above mentioned; mix them well together, and thus add all the rest of the lime-water in succession. The reason of adding the lime-water thus by portions, is, that if it be poured in all at once, it will not mix with the benzoin, which will likewise coagulate and run together into a mass. This mixture must be boiled over a gentle fire for half an hour, agitating it constantly; then taking it from the fire, let it stand quiet for some time to settle, after which the clear liquor is to be poured off into a glass vessel. Pour then eight pounds of water more upon the lime in the vessel, and use this lime-water as before, repeating this process twice more, making four times

in all; and lastly, putting all the residuums together on a filter, pour hot water upon them. During this process, the calcareous earth of the lime-water combines with the acid of benzoin, and separates it from the resinous particles of this substance; but a small quantity of resin is dissolved by the lime-water, and gives it a yellow colour.

"All these liquors being mixed together and boiled down to two pounds, are then to be strained into another glass vessel. They are inspissated so far, because the superfluous water would hold a great quantity of the salt in solution; and a little of the resin being soluble in a large quantity of lime-water, but not in a small, falls to the bottom on the liquor being inspissated. When the liquor has become cold, after being strained the last time, add muriatic acid till the flowers be totally precipitated, which happens by reason of the stronger attraction of the marine acid for the calcareous earth. The precipitated coagulum is then to be put upon a filter; and, after being well dried, to be edulcorated sufficiently, by repeatedly pouring cold water upon it, when it must be dried with a gentle heat. As the water made use of for this purpose, however, is capable of dissolving a little of the salt of benzoin, it ought to be evaporated, and afterwards set to crystallize. In order to give this salt a shining appearance, let it be dissolved in a sufficient quantity, six ounces, for instance, of water by gentle boiling; then strain it immediately, while yet warm, through a cloth, into a glass vessel which has been heated before; and thus a number of fine crystals will shoot as soon as the solution is grown cold. The water is then to be strained from the crystals, and the rest of the salt suspended in the water may be obtained by repeated evaporation and crystallization. In this method, however, a great quantity of the flowers are lost by reason of their volatility; it will therefore be more convenient to keep them in the form of their original precipitate, which is always in fine powder. Cloth answers best for the filtration of the hot solution: when blotting paper is used, the salt sometimes crystallizes in the filter, and obstructs it. The filtration itself might be omitted, were it not that about two grains of resin of benzoin remain united to the liquor, from whence it cannot be separated but by the operation just mentioned." — The properties of this salt as an acid are but little known. It has a most agreeable flavour; which, however, ceases as soon as it unites with calcareous earth, but is recovered again on being separated by any other acid.

993
Anortalous
vegetable
acids how
divided.

994
Of the essential
acids.

995
Empyreumatic
acids.

With regard to the other vegetable acids, they may be divided into the essential, the fermented, and empyreumatic. The essential acids are pure, as exemplified in those of lemons, sorrel, and sorrel-dock; or but little altered by the admixture of other matters, as those of cherries, barberries, tamarinds, &c. In sweet fruits, they are generally so much covered when ripe as scarce to be distinguished: however, these latent acids become more evident, partly in fermentation, and partly by dry distillation. By the former method, all flowers, excepting a few which bear cruciform flowers, are made to yield vinegar; and by dry distillation only a very few yield a volatile alkali.

The acid which passes over in dry distillation is scarce perceptible while the subject retains its natural

No 73.

form; but when once produced, has the same essential qualities with the other; whence it was naturally supposed, that all vegetable acids are at bottom the same. Chemists, however, have been divided in their opinions on this subject; some supposing that the acid of sugar or tartar is the basis, and others that vinegar is the basis of them all. In proof of this latter hypothesis, it has been urged, that the acid of lemons may be crystallized; of which we have the following account in Scheele's Essays. "The juice will not shoot into crystals by mere evaporation, even when thickened to the consistence of a syrup. This our author supposed to proceed from the great quantity of mucilaginous matter with which the juice abounds; for which reason he mixed the inspissated juice with strong spirit of wine, which coagulated the whole: but even thus he could obtain no crystals by evaporation. He therefore employed the method used for procuring the pure acid of tartar, and which is formerly described. The lemon juice, while boiling, was saturated with pulverised chalk, and the compound immediately fell to the bottom in a form nearly resembling tartarified lime. To separate the acid, a quantity of oil of vitriol, equal in weight to the chalk employed, but diluted with ten times its weight of water was necessary. This mixture must be boiled in a glass vessel for a few minutes; and when grown cold, the acid is to be separated from the gypsum by filtration. In order to crystallize it, we must evaporate the whole to the consistence of a thin syrup; but great care is to be taken lest any of the calcareous earth remain in the evaporated liquor: to determine which, a little of it is to be tried with fresh oil of vitriol, which will throw down the remainder: and in this case some more must be added to the whole quantity; for the least particle of lime remaining prevents the crystallization, while the superfluous quantity of oil of vitriol, if too much happens to be added, remains in the liquor. The crystals shoot equally well in a hot as in a cold temperature, which is very unusual."

It is very remarkable that this crystallized salt of lemons cannot be converted into acid of sugar by means of that of nitre, though the extract of the juice itself may. Sour cherries afford acid of sugar, and another salt supposed to be tartar; and a kind of sugar may be obtained not only from roots of various kinds, but from fine raisins, and, as Dr Crell thinks, from expressed must; but whether the saccharine acid can be procured from this kind of sugar in equal quantity as from the common, or even whether it yields the same products with common sugar by dry distillation, is still a matter of doubt.

Pure acid of tartar yields on distillation *per se* an empyreumatic acid, and a coal consisting of oily particles and calcareous earth. Dr Crell therefore asks, May not the acetous acid be mere acid of tartar, which did not meet with alkaline salt and earth enough with which it might combine and become more fixed; but, on the contrary, attracted more subtle oily particles, and thus became more volatile? In distilling terra foliata tartari in the dry way, the acid of vinegar which enters its composition is almost entirely destroyed, only $\frac{1}{100}$ th of pure acid being obtained, the residuum in the retort, as well as the rest of that which comes over into the receiver, being entirely alkaline; and the

same thing happens to the acid of tartar, the empyreumatic acid above mentioned being extremely weak. Mr Beaumé likewise informs us, that if any calcareous earth, egg-shells, for instance, be dissolved in vinegar, and the crystallized salt be distilled, we obtain $\frac{2}{3}$ of a red and very fiery inflammable fluid, smelling like empyreumatic acetous ether, which reddens tincture of turnsole. Must, distilled before fermentation, yields only an empyreumatic acid resembling spirit of tartar. The conjecture therefore seems reasonable, that vinegar and tartar have for their basis the same species of acid, which in the case of vinegar is combined with a greater proportion of oil, and in tartar with more earth. To bring vinegar therefore nearer the state of tartar, we must deprive it of its fine volatilizing phlogiston, combine it with more fixed matter, and restore its grosser oil. All this, however, is extremely difficult to be effected. Mr Westrumb, who attempted it, added nitrous acid in various proportions, but could only produce a phlogistication of the latter, and dephlogistication of the vinegar; but as he could not think of any method of separating the two acids from one another, he was unable to investigate the properties of vinegar thus dephlogisticated. Dr Crell is of opinion, that this might have been done by vegetable alkali, lime, and terra ponderosa. The nitrous acid, with vegetable alkali, would have shot into the ordinary hexangular crystals of nitre: the acetous acid would have formed a compound not easily crystallized, provided it had remained unchanged; and, though it had approached the nature of saccharine acid, would still have formed a compound difficultly crystallizable. The effects of these acids, indeed, on lime, are directly opposite to what they are on terra ponderosa. With the former, nitrous acid forms a liquor which can scarce be crystallized; with the latter, it produces salts difficult to be dissolved: while the acetous acid, with terra ponderosa, forms deliquescent salts; with lime, such as effloresce in the air. But if the vinegar, by means of the operation already mentioned, had been made to approach towards the nature of acid of sugar, transparent crystals would immediately have fallen, by reason of the strong attraction of this acid for lime. Dr Crell therefore recommends the following method. Let nitrous acid be several times distilled off from vinegar; and when the former, upon being newly added, produces no more red vapours, saturate the liquor with lime or terra ponderosa, separating the ley, which will not shoot, from the crystals. The nature of the salt which does not contain nitrous acid, may be determined from the figure of its crystals, or from the effects of other salts in consequence of a double elective attraction. We might likewise add fresh nitrous acid to the separated salt, or to the whole mixture, without any separation of the nitrous salt, till the earthy salt, which does not contain any nitrous acid, be saturated. The vinegar, if unaltered by the operation, would rise on distilling the liquor; and if converted into saccharine acid, would not be dislodged from lime by spirit of nitre. In like manner, distilled vinegar should be saturated with chalk, the compound reduced to crystals, and then exposed to as strong a fire as it can bear without expelling the acid, in order to dis-

ment.

sipate some phlogistic particles. Let it then be dissolved, filtered, and crystallized again; after which it may be treated with nitrous acid as above directed. "Perhaps (says Dr Crell), the acetous acid may by this combination acquire more fixity; so that the nitrous acid shall be able to produce a greater change. Should it pass over again in the form of acetous acid unchanged, let it be combined once more with calcareous earth; and let the foregoing experiment be repeated, in order to try whether some sensible change will not ensue. Should this method fail, try the opposite; that is, endeavour to add more gross phlogistic matter to the vinegar. Try to combine strong vinegar, and that which has been distilled, with unctuous oils. Thus we might perhaps bring it nearer to tartar; and, again, by means of nitrous acid, convert it into acid of sugar.

In another dissertation on this subject, Dr Crell undertakes to show, that all the vegetable acids may be converted into one, and that this is contained in the purest spirit of wine. The following are adduced as proofs.

1. If the residuum of dulcified spirit of nitre be boiled with a large quantity of nitrous acid, care being taken at the same time to condense the vapours by a proper apparatus; and if the liquid which has passed over be saturated with vegetable alkali, nitre and terra foliata tartari will be obtained; and on separating the latter by means of spirit of wine, the vinegar may be had in the ordinary way of decomposing the salt.

2. On boiling the residuum over again with nitrous acid, the same products are obtained; and the more frequently this process is repeated, the less acid of sugar is procured, until at length no vestige of it is to be met with.

3. Pure acid of sugar, boiled with 12 or 14 times its quantity of nitrous acid, is entirely decomposed, and the receiver is found to contain phlogisticated nitrous acid, vinegar, fixed air, and phlogisticated air, while a little calcareous earth remains in the retort.

4. Acid of sugar is likewise decomposed by boiling with six times its quantity of vitriolic acid. In the receiver we find vinegar, phlogisticated vitriolic acid, aerial acid; while pure vitriolic acid remains in the retort.

5. By saturating the residuum of dulcified spirit of nitre with chalk, there is formed an insoluble salt, which by treatment with vitriolic acid yields a real acid of tartar, constituting a cream of tartar with vegetable alkali.

6. On evaporating the liquor from which the tartareous selenite was obtained, a dark-coloured matter remains, yielding on distillation an empyreumatic acid of tartar, and a spongy coal. Hence it would seem, that spirit of wine consists of acid of tartar, of water, and phlogiston; so that it is a native dulcified acid: and nitrous acid, on being mixed with it in moderate quantity, dislodges the acid of tartar. On the addition of more nitrous acid, the acid of tartar is resolved into acid of sugar and phlogiston; and by a still greater addition, the saccharine acid is changed into vinegar.

7. On boiling one part of acid of sugar with one and an half of manganese and a sufficient quantity of

Acid of Fat. nitrous acid, the manganese will be almost entirely dissolved, and phlogisticated nitrous acid along with vinegar will pass over into the receiver.

8. On boiling together acid of tartar, manganese, and nitrous acid, we obtain a solution of the manganese, with phlogisticated nitrous acid and vinegar as before.

1013
From the digestion of acid of tartar with spirit of wine.

9. If acid of tartar be boiled along with vitriolic acid and manganese, the latter will be dissolved, and vinegar with vitriolic acid will pass over into the receiver.

1014
From the solution of manganese with vitriolic acid and spirit of wine.

10. On digesting acid of tartar and spirit of wine for several months, the whole is converted into vinegar; the air in the vessel being partly converted into cretaceous acid, and partly into phlogisticated air.

1015
From the distillation of spirit of wine with caustic alkali.

11. On boiling spirit of wine with vitriolic acid and manganese, it will be converted into vinegar and phlogisticated air.

12. By distilling spirit of wine upwards of 20 times from caustic alkali, it was changed into vinegar, and a considerable quantity of water was obtained.

Hence it appears, says Dr Crell, that the acids of tartar, sugar, and vinegar, are modifications of the same acid, as it contains more or less phlogiston. The acid of tartar has the greatest quantity, the acid of sugar somewhat less, and vinegar the least of all. In these experiments, however, care must be taken that neither the nitrous acid nor fixed alkali employed contain any marine acid, otherwise the results will be uncertain.

§ 18. Of the Acid of Fat.

2d 1015
How procured.

THIS may be obtained from fuet by means of many repeated distillations. A small quantity is separated at each distillation; but by distilling the empyreumatic oil into which the fuet is thus converted over and over, a fresh quantity is always obtained. The acid of fat in some respects has a resemblance to that of sea-salt; but in others is much more like the vegetable kind, as being destructible in a strong fire, forming compounds which do not deliquesce with calcareous earth, and uniting intimately with oily substances. With alkalies it forms salts entirely different from those yielded by the other acids; with the volatile alkali, particularly, it produces a concrete volatile salt. When saturated with calcareous earth, it yields brown crystals; and a salt of the same kind was obtained by Dr Crell from a mixture of quicklime and fuet distilled to dryness, and boiling up the residuum with water. The crystals were hexagonal, and terminated by a plane surface; their taste was acrid and saltish; they did not deliquesce in the air, and were easily and copiously dissolved in water. With magnesia and earth of alum a gummy mass is obtained, which refuses to crystallize.

3d 1015
Its effects on alkalies, &c.

4th 1015
On metals.

With regard to the metals, Dr Crell informs us, that the acid of fat copiously dissolves manganese into a clear and limpid liquor. It dissolves the precipitate of cobalt, but not the regulus. White arsenic is acted upon but sparingly, and nickel not at all, though it forms a green solution with the precipitate from nitrous acid. Regulus of antimony, by the assistance of heat, is dissolved into a clear liquor, which became milky in the cold: it crystallized on evaporation,

and did not deliquesce in the air. Zinc readily dissolved, and imparted a peculiar metallic taste, falling to the bottom in the form of a white powder on the addition of an alkali. Bismuth in the metallic state was not dissolved; but the precipitate was. It acted upon mercury after being twice distilled from it, and poured afresh upon the metal. The mercury could not be entirely precipitated by common salt. It acted more vigorously upon a precipitate from corrosive sublimate; from the solution of which a white sublimate was obtained after the liquor had been drawn off by distillation. A gold-coloured solution was obtained from platina by distilling the acid from it to dryness, and then pouring it back again; the precipitate of this metal from aqua-regia by spirit of wine was dissolved in great abundance. Iron was very easily dissolved in it, and exhibited a liquor of an astringent taste, which shot into needle-like crystals that did not deliquesce in the air. Lead was corroded, and rendered the acid turbid. Minium was converted into a white powder, and then dissolved with greater ease. The solution has a sweet taste, and cannot be precipitated by sea-salt. Tin was corroded into a yellow calx, and dissolved but in very small quantity. Copper was dissolved, even in the cold, into a green liquor; but the solution was greatly promoted by heat. On evaporation it showed some disposition to crystallize, but again attracted moisture from the air. Silver-leaf was attacked only in a very small degree; however, some was precipitated by means of copper, and the marine acid rendered the liquor turbid. The calx precipitated from aquafortis was dissolved more copiously. Silver was precipitated of a white colour from aquafortis by the pure acid itself, as well as by its ammoniacal salt. Half an ounce of the acid distilled four times almost to dryness from some gold leaves, and at length poured back upon them, the precipitate of a dilute solution of tin obtained by it, gained only a faint colour, rather inclining to red; but a mixture of two parts of acid with one of aquafortis, dissolved gold very readily.

§ 19. Of Fixed ALKALINE SALTS.

1016
How procured.

OF these there are two kinds; the vegetable and mineral. The former is never found by itself, and but rarely in combination with any acid; but is always prepared from the ashes of burnt vegetables. It is got in the greatest quantity from crude tartar; from which, if burned with proper care and attention, we may obtain one pound of alkali out of $2\frac{1}{2}$ of the tartar. The latter is found native in some parts of the earth. It is likewise found in very large quantities combined with the marine acid, in the waters of the ocean, and in the bowels of the earth; thus forming the common alimentary salt. It is also produced from the ashes of certain sea-plants, and of the plant called *kali*; from whence both the mineral and vegetable alkalies have taken their name.

1017
Vegetable alkali crystallized.

The vegetable alkali difficultly assumes a crystalline form; nevertheless, it may be partially united with some acids in such a manner as to crystallize, and lose its property of deliquating in the air, without, at the same time, ceasing to be an alkali. Of this we have an example in the acid of ants above mentioned. Something

Fixed Alkaline Salts and their Combinations.

1021
Hepar sulphuris.

thing of the same kind we have observed in treating vegetable fixed alkali with spirit of wine. A gallon of pretty strong spirit of wine being drawn over from a pound of salt of tartar, a black unctuous liquor was left, which shot into crystals very much resembling vitriolated tartar, and which did not deliquesce in the air, but were nevertheless strongly alkaline. Dr Black, however, informs us, that the vegetable alkali may be shot into fine crystals; but which cannot be preserved, on account of their great attraction for moisture, unless closely shut up from the air. They have not such a quantity of water as to undergo the aqueous fusion.

The mineral alkali in its natural state always assumes a crystalline form, somewhat resembling that of sal mirabile. It does not deliquesce in the air, nor does it seem to have so strong an attraction for water, even when in its most caustic state, as the vegetable alkali: hence mineral alkali is preferable to it in making soap, which is always of a firmer consistence with mineral than with vegetable alkali. If vegetable alkali is combined with spirit of salt, some change seems to be thereby induced upon it; as the salt produced by expelling the marine acid by means of the vitriolic, and then crystallizing the mass, crystallizes differently from vitriolated tartar. Whether the vegetable alkali might by this means be entirely converted into the mineral, deserves a further inquiry.

Both mineral and vegetable alkalies, when applied to the tongue, have a very sharp, pungent, and urinous taste; but the vegetable considerably more so than the mineral. They both unite with acids, and form different neutral salts with them: but the vegetable alkali seems to have rather a greater attraction for acids than the other; although this difference is not so great as that a neutral salt, formed by the union of mineral alkali with any acid, can be perfectly decomposed by an addition of the vegetable alkali, unless in considerable excess.

Both vegetable and mineral alkali appear to be composed of an exceedingly caustic salt united with a certain quantity of fixed air. This may be increased so far, as to make the vegetable alkali assume a crystalline form, and lose great part of its alkaline properties: but as the adhesion of great part of this air is very slight, it easily separates by a gentle heat. Some part, however, is obstinately retained; and the alkali cannot be deprived of it by the most violent calcination *per se*. The only method of depriving it entirely of its fixed air is, by mixing an alkaline solution with quicklime.

Fixed Alkalies COMBINED,

1. *With Sulphur.* The produce of this is the red fetid compound called *hepar sulphuris*, or liver of sulphur. It may be made by melting sulphur with a gentle heat, and stirring into it, while melted, four times its weight of dry alkaline salt. The whole readily melts and forms a red mass of a very fetid smell, and which deliquesces in the air. If sulphur is boiled in a solution of fixed alkaline salt, a like combination will take place.

In this process, when the *hepar* is made either in the dry or the moist way, the fixed air of the alkali is discharged, according to Dr Priestley's observation. Neither does a fixed alkali, when combined with fixed air, seem capable of uniting with sulphur; nor will

the union be accomplished without heat, unless the alkali is already in a caustic state. Hence a cold solution of *hepar sulphuris* may be decomposed, partly at least, by fixed air. On adding an acid, however, the decomposition takes place much more rapidly; and the sulphur is precipitated to the bottom, in form of a white powder.

During the precipitation of the sulphur from an alkali, by means of acids, a thick white smoke arises, of a most fetid smell and suffocating nature. It burns quietly, without explosion, on a candle's being held in it. Calces of silver, lead, iron, or bismuth, are rendered black by it. Hence, if any thing is wrote with a solution of lead, and a solution of *hepar sulphuris* is passed over it when dry, the writing, formerly invisible, will immediately appear of a blackish brown colour. Silver, in its metallic state, is prodigiously blackened either by the contact of this vapour, or by being immersed in a solution of the *hepar sulphuris* itself. Litharge is instantly restored to its metallic state, on being immersed even in a cold solution of *hepar sulphuris*.

By being united with an alkali, the acid of sulphur seems very much disposed to quit the phlogiston. If a solution of *hepar sulphuris* is exposed to the air for some time, it is spontaneously decomposed; the phlogiston of the sulphur flying off, and the acid remaining united with the alkali into a vitriolated tartar. This decomposition takes place so remarkably, when liver of sulphur is dissolved in water, that, by a single evaporation to dryness, it will be almost totally changed into vitriolated tartar. If this substance, in a dry state, be exposed to a moderate degree of heat, and the mass kept constantly stirring, a like decomposition will follow; the phlogiston of the sulphur will fly off, and the acid unite with the alkali.

Liver of sulphur is a great solvent of metallic matters; all of which, except zinc, it attacks, particularly in fusion. It seems to dissolve gold more effectually than other metals. This compound also dissolves vegetable coals, even by the humid way; and these solutions, if suffered to stand in the open air, always precipitate a black powder, no other than the coal they had dissolved, in proportion to the quantity of *hepar sulphuris* decomposed. When vegetable coal is thus dissolved by liver of sulphur in fusion, it is of a much deeper red than in its natural state. The solution in water is of a green colour.

II. *With Expressed Oils.* The result of this combination is *soap*; for the preparation of which in large quantities in the way of trade, see SOAP. The soap which is used in medicine is prepared without heat, in the following manner, according to the author of the Chemical Dictionary.

"One part of quicklime, and two parts of good Spanish soda (the salt prepared from the ashes of the herb kali), are boiled together during a short time in an iron caldron. This lixivium is to be filtered, and evaporated by heat, till a phial, capable of containing an ounce of water, shall contain an ounce and 216 grains of this lixivium. One part of this lixivium is to be mixed with two parts of oil of olives, or of sweet almonds, in a glass or stone-ware vessel. The mixture soon becomes thick and white; and must be stirred from time to time with an iron spatula. The combination

1026
Soap.

Fixed Alkaline Salts and their Combinations.

nation is gradually completed, and in seven or eight days a very white and firm soap is obtained."

In attempting combinations of this kind, it is absolutely necessary that the alkali be deprived of its fixed air as much as possible; otherwise the soap will be quite unctuous and soft: for fixed alkalies have a greater attraction for fixed air than for oil, and hence soap is decomposed by blowing fixed air into a solution of it in water. It may be made either with tallow, wax, spermaceti, butter of cocoa, the coarser resinous substances, or animal oils.

1027
Starkey's
soap.

III. *With Essential Oils.* The volatility of these oils in a great measure hinders them from being acted upon by alkalies: nevertheless, combinations of this kind have been attempted; and the compounds so produced have been called *Starkey's soap*, from one Starkey a chemist, who endeavoured to volatilize salt of tartar by combining it with oil of turpentine. His method was to put dry salt of tartar into a matrafs, and pour upon it essential oil of turpentine to the height of two or three fingers breadth. In five or six months, a part of the alkali and oil were combined into a white saponaceous compound. This must be separated from the mixture, and more of it will afterwards be formed by the same method.

Chemists, imagining this soap to be possessed of considerable medical virtues, have endeavoured by various methods to shorten this tedious process. Of these one of the most expeditious is that recommended by Mr Beaumé; which consists in triturating, for a long time, alkaline salt upon a porphyry, and adding oil of turpentine during the trituration. According to him, the thick resinous part of the oil only can combine with the salt; and, during the time this combination is effected, the more subtle and attenuated parts will fly off. Hence he finds that the operation is considerably abridged by the addition of a little turpentine or common soap. The most expeditious of all, however, is that mentioned by Dr Lewis; which consists in heating the alkali red hot, and then throwing it into oil of turpentine, stirring them well together; on which they immediately unite into a saponaceous mass.

This kind of soap is subject to great alterations from keeping; particularly the loss of its colour, and a kind of decomposition occasioned by the extraction of an acid from the oil of turpentine, which unites with the alkali, and crystallizes not only all over the surface, but in the very substance of the soap. The nature of this salt is unknown, but certainly deserves consideration.

1028
Phlogisticated alkalies.

IV. *With Phlogiston.* This combination is effected by calcining them with the charcoal either of vegetable or animal matters. The consequence is, that they are greatly altered in their properties; sometimes so much as to be enabled to precipitate calcareous earths from their solutions in acids. Metallic solutions precipitated by them in this state, assume different colours.

Differences observed between Fixed Alkalies obtained from different *Vegetables*.

These differences we must conceive to arise from some proportion of the oily and phlogistic matter of the vegetable remaining in the ashes from whence the salts are extracted; for when reduced to their utmost

purity, by repeated calcinations in a strong fire, and deliquations in the air, all of them, the marine alkali excepted, appear to be the very same.

On this subject Mr Gmelin has given a great number of experiments in the fifth volume of the *Commentaria Petropolitana*; and found very considerable differences, not only between the alkaline salts, but likewise the pure vegetable earths obtained from different vegetables by burning. The salts of the several plants examined were prepared with great care, and all of them exactly in the same manner; each vegetable being burnt in a separate crucible, with the same degree of fire, till no remains of coaly matter could any longer be perceived; and the ashes elixated in glass vessels with cold distilled water. The salts, thus obtained, were found to produce different colours on mixture with certain liquors, and to effervesce in very different degrees with acids: certain metallic solutions were by some precipitated, by others only rendered thicker, by others both precipitated and rendered thick; whilst some occasioned neither the one nor the other of these changes, but left the fluid clear and transparent. Thus, with the vitriolic acid, the salts of southernwood and sage struck a pale brown colour; those of pine-tops and rue, a yellow; that of fern, a reddish yellow; and that of sanicle, a dark leek-green: that of dill yielded a leek-green precipitate, with elegant green flakes floating in the liquor. This last salt also gave a greenish precipitate with the marine acid, and a red one with the nitrous. Solution of corrosive sublimate was changed yellow by salt of southernwood; of a brownish colour, by that of colt's-foot; of a deep red, by that of wormwood; and of a pitch-colour, by that of dill. That of fern threw down an opal-colour; of sage, a sulphur-yellow; of elder flowers, a citron yellow; of sanicle, a saffron colour; and of milfoil, a deep-red precipitate. From solution of silver, salt of *carduus benedictus* threw down a white; of camomile, a grey; of hyssop, a brownish; of dill, a blackish brown; of scabious, a yellowish; and that of pine-tree tops, a sulphur yellow precipitate. Solution of vitriol of copper was changed by salt of southernwood to a bright sea-green; by that of dill, to an unsightly green; of agrimony, to a greenish blue; and by that of milfoil, to a bright sky-blue: the salt of penny-royal made the liquor thick as well as blue, and that of feverfew made it thick and green: the salt of hyssop threw down a green precipitate, that of scurvy-grass a blue one, and that of fumitory a greenish blue: whilst the salt of fern made scarcely any change either in the colour or consistency of the liquor.

Fixed Alkaline Salts and their Combinations.

1029
Mr Gmelin's experiments.

§ 19. Of Volatile Alkali.

This is a kind of salt obtained from all animal, some vegetable, substances, from foot by distillation with a strong heat, and from all vegetable substances by putrefaction. Though a volatile alkali is procurable from all putrid animal substances by distillation, yet the putrefactive process does not seem to prepare volatile alkali in all of these. Putrid urine, indeed, contains a great quantity of alkali ready formed, whence its use in scouring, &c. but the case is not so with putrid blood or flesh. These afford no alkali till after the phlegm has arisen; and this they would

1030
Whence obtained.

Volatile
Alkali and

nations.

Volatile
Alkali and
its Combi-
nations.

would do, though they had not been putrefied. According to Mr Wiegleb, volatile alkali is found in limestone, lapis fuillus, chalk, marble, coals, turf, loam, clay, and many other kinds of earth. Its existence in these substances may be discovered merely by distilling them with a brisk fire, but still better by the addition of some quantity of fixed alkali or quicklime before the distillation.—It has even been found in all mineral salts and their acids, as vitriol, nitre, common salt, and the acid liquors drawn from these substances, also in gypsum and sulphur; from all which it may be separated by means of quicklime.—In the vegetable kingdom it is produced by dry distillation from mustard-seed, elder flowers and leaves; the leaves of the wild cherry tree, white water-lilies, tobacco, and sage; as well as from many other plants. According to our author, the plainest proof of its existing almost universally in the vegetable kingdom, is, that the foot of our chimneys affords a volatile alkali by distillation, either with or without quicklime.

Volatile alkali, when pure, appears of a snowy whiteness; has a very pungent smell, without any disagreeable empyreuma; is very easily evaporable, without leaving any residuum; effervesces with acids much more strongly than fixed alkali; and forms with them neutral compounds called *ammoniacal salts*, which we have already described, and which are different according to the nature of the acid made use of; for all volatile alkalies, when perfectly purified, appear to be the very same, without the smallest difference.

Like fixed alkalies, these salts contain a great quantity of fixed air, on which their solidity depends; and which may be so increased as perfectly to neutralize, and deprive them of their peculiar taste and smell. When neutralized by fixed air, they have a very agreeable pungent taste, somewhat resembling that of weak fermenting liquors. When totally deprived of fixed air, by means of lime, they cannot be reduced to a solid form; but are dissipated in an invisible and exceedingly pungent vapour, called by Dr Priestley *alkaline air*. When volatile alkaline salt is dissolved in water, the solution is called a *volatile alkaline spirit*.

Distillation and Purification of Volatile Alkalies.

1031
Distilling
vessel, and
method of
performing
the opera-
tion.

The materials most commonly used for preparing volatile alkalies are the solid parts of animals, as bones, horns, &c. These are to be put into an iron pot of the shape recommended for solution; to this must be fitted a flat head, having a hole in the middle about two inches diameter. From this a tube of plate-iron must issue, which is to be bent in such a manner that the extremity of it may enter an oil jar, through an hole made in its upper part, and dip about half an inch under some water placed in the lower part. The mouth of the jar is to be fitted with a cover, luted on very exactly; and having a small hole, which may be occasionally stopped with a wooden peg. The junctures are to be all luted as close as possible, with a mixture of clay, sand, and some oil; and those which are not exposed to a burning heat, may be further secured by quicklime and the white of an egg, or by means of glue. A fire being now kindled, the air contained in the distilling vessel is first expelled, which is known by the bubbling of the water; and to this vent must be given by pulling out the wooden peg. A considerable quantity of phlegm will then come over, along with some volatile

alkali, a great quantity of fixable air, and some oil. The alkali will unite with the water, and likewise some part of the fixed air; the oil swimming above. A great many incoercible vapours, however, will come over, to which vent must be given from time to time, by pulling out the peg. The distillation is to be continued till all is come over; which may be known by the cessation, or very slow bubbling of the water. The iron-pipe must then be separated from the cover of the distilling vessel, lest the liquid in the jar should return into it, on the air being condensed by its cooling. In the jar will be a volatile spirit, more or less strong according as there was less or more water put in, with an exceedingly fetid black oil floating upon it.

The rectification of the volatile alkali is most commodiously performed at once by combining it with an acid; and, as spirit of salt has the least affinity with inflammable matter, it is to be chosen for this purpose, in preference to the vitriolic or nitrous. As the spirit is excessively oily, though already much weakened by the admixture of the water in the jar, if a very large quantity was not originally put in, an equal quantity of water may still be added, on drawing off the spirit. That as little may be lost as possible, the spirit should be received in a stone bottle; and the marine acid, likewise in a distilled state, added by little and little, till the effervescence ceases. The liquor, which is now an impure solution of sal ammoniac, is to be left for some time, that the oil may separate itself; it is then to be filtered, evaporated, and crystallized in a leaden vessel. If the crystals are not sufficiently pure at the first, they will easily become so on a second dissolution.

From sal ammoniac thus obtained pure, the volatile alkali may be extricated by distillation with chalk, alkaline salts, or quicklime. Alkaline salts act more briskly than chalk, and give a much stronger volatile alkali. The strength of this, however, we know may be altered at pleasure, by adding to, or depriving it of, its natural quantity of fixed air. Hence, perhaps, the best method would be, to prepare volatile alkalies altogether in a fluid state, by means of quicklime; and then add fixed air to them, by means of an apparatus similar to that directed by Dr Priestley for impregnating water with fixed air. To prevent lime from adhering to the distilling vessels in which it is put, the translator of Wiegleb's chemistry recommends the putting in three or four ounces of common salt along with the other ingredients.

Volatile alkalies COMBINED,

I. *With Metals.* There are only three metals, *viz.* copper, iron, and lead, upon which, while in their metallic form, volatile alkalies are capable of acting. Copper-filings are dissolved by volatile alkali, especially in its caustic state, into a liquor of a most admirable blue colour. It is remarkable, that this colour depends entirely upon the air having access to the solution: for if the bottle containing it is close stopt, the liquor becomes colourless; but, however, resumes its blue colour on being exposed to the air. On evaporation, a blue saline mass is obtained, which, mixed with fats, or other inflammable matters, tinges their flame green, leaving a red calx of copper, soluble again in volatile spirits as at first. This saline substance

Copper,
fulmina-
ting.

stance has been received into the last edition of the Edinburgh Dispensatory, under the name of *cuprum ammoniacale*, as an antiepileptic.

The blue mixture of solution of copper in aquafortis with volatile spirits, yields sapphire-coloured crystals, which dissolve in spirit of wine, and impart their colour to it. If, instead of crystallization, the liquor be totally evaporated, the remaining dry matter explodes, in a moderate heat, like aurum fulminans. This is given as a fact by Dr Lewis; but hath not succeeded upon trial by Dr Black. Various phenomena, says Mr Wiegleb, occur in the dissolution of copper by the volatile alkali.—On saturating dilute spirit of sal ammoniac with copper-filings, crystals are formed of a dark-blue colour, but which, by exposure to the air, fall to pieces and become green. Vinous spirit of sal ammoniac impregnated with copper, loses in an instant its blue colour, on the affusion of an equal quantity of saturated solution of fixed alkaline salt. The copper is then taken up by the fixed alkaline solution, which of consequence acquires a blue colour, while the spirit of wine, deprived of the metal, floats clear on the top. When filings of copper are put into a bottle, and that bottle quite filled with caustic volatile alkali, and is immediately stopped up, no solution takes place: but when the bottle is left open, only for a short time, or an empty space is left in it, a colourless solution is obtained, which in the air obtains a blue colour; but which may be deprived of this colour as often as we please, by shutting it up exactly from the air, and letting it stand, in this situation, on fresh filings of copper.—From these phenomena Mr Wiegleb concludes, that copper does not dissolve in volatile alkali until it has lost part of its phlogiston, to which the air, by the attraction it exerts upon it, contributes its share. If this has taken place only in a small proportion, and the farther access of air be prevented, the remainder will be dissolved without any colour; which, however, appears in the instant that, by a fresh accession of air, the phlogiston still remaining finds means to escape. The dissolved copper is always precipitated when the solution meets with phlogisticated copper. The colourless solution is precipitated by zinc and vitriolic acid, but not by iron. It tastes rather sweet, and does not smell very strong of volatile alkali; while, on the contrary, the blue solution has a pungent smell, and is precipitated by distilled water.

On the other two metals the action of volatile alkali is by no means so evident; it dissolves iron very slowly into a liquor, the nature of which is not known; and lead is corroded by it into a mucilaginous substance.

II. *With Inflammable Substances.* With expressed oils, the caustic volatile alkali unites into a soft unctuous mass, of a very white colour, imperfectly soluble in water, and which is soon decomposed spontaneously. Compositions of this kind are frequently used for removing pains, and sometimes with success. With essential oils, volatile alkalies may be united, either in their dry or liquid form, by means of distillation. The produce is called *sal volatile oleosum*; it is much more frequently used in a liquid than in a dry form. The general method of preparation is by distilling volatile alkali along with essential oils and spirit of wine, or the aromatic substances from whence

the essential oils are drawn. These compositions are variable at pleasure; but certain forms are laid down in the dispensatories, with which it is expected that all the chemists should comply in the preparation of these medicines.

III. *Eau de Luce.* This is the name given to an exceedingly volatile spirit, which some years ago was pretty much in vogue; and indeed seems very well calculated to answer all the purposes for which volatile alkalies can be used. It was of a thick white colour, and smelled somewhat of oil of amber. A receipt appeared in Lewis's Dispensatory for the preparation of this fluid, under the name of *spiritus volatilis succinatus*. The method there directed, however, did not succeed; because, though the alkaline spirit is capable of keeping a small quantity of oil of amber suspended, the colour is greatly more dilute than that of genuine eau de luce. In the Chemical Dictionary we have the following receipt: "Take four ounces of rectified spirit of wine, and in it dissolve 10 or 12 grains of white soap; filter this solution; then dissolve in it a drachm of rectified oil of amber, and filter again. Mix as much of this solution with the strongest volatile spirit of sal ammoniac, as will be sufficient, when thoroughly shaken, to give it a beautiful milky appearance. If upon its surface be formed a cream, some more of the oily spirit must be added."

This receipt likewise seems insufficient. For the oil of amber does not dissolve in spirit of wine: neither is it probable that the small quantity of soap made use of could be of any service; for the soap would dissolve perfectly in the alkaline spirit, without suffering any decomposition. The only method which we have found to answer is the following. Take an ounce, or any quantity at pleasure, of balsamum Canadense; place it in a small china basin, in a pan of boiling water, and keep it there till a drop of it taken out appears of a resinous consistence when cold. Extract a tincture from this resin with good spirit of wine; and having impregnated your volatile spirit with oil of amber, lavender, or any other essential oil, drop in as much of the spiritous tincture as will give it the desired colour. If the volatile spirit is very strong, the eau de luce will be thick and white, like the cream of new milk; nor is it subject to turn brown with keeping.

IV. *With Volatile Tincture of Sulphur.* This is a combination of the caustic volatile alkali, or spirit of sal ammoniac, with sulphur. It is usually directed to be made by grinding lime with the sulphur, and afterwards with the sal ammoniac, and distilling the whole in a retort; but the produce is by this method very small, and even the success uncertain. A preferable method seems to be, to impregnate the strongest caustic volatile spirit with the vapour which arises in the decomposition of hepar sulphuris by means of an acid, in the same manner as directed for impregnating water with fixed air.

This preparation has a most nauseous fetid smell, which spreads to a considerable distance; and the effluvia will blacken silver or copper, if barely placed in the neighbourhood of the unstopped bottle. This property renders it capable of forming a curious kind of sympathetic ink; for if paper is wrote upon with a solution of saccharum saturni, the writing, which disappears when dry, will appear legible, and of a brownish

brownish black, by barely holding it near the mouth of the bottle containing volatile tincture of sulphur. The vapours of this tincture are so exceedingly penetrating, that it is said they will even penetrate through a wall, so as to make a writing with saccharum saturni appear legible on the other side; but this is much to be doubted. It is even said that it cannot penetrate through the substance of paper, but only insinuates itself betwixt the leaves; and hence if the edges of the leaves are glued together no black colour will appear.

§ 20. *Of the PHENOMENA resulting from different mixtures of the Acid, Neutral, and Alkaline SALTS, already treated of.*

1040
Of mixing the acid spirits with one another.

1. If concentrated oil of vitriol is mixed with strong spirit of nitre, or spirit of salt, the weaker acid will become exceedingly volatile, and emit very elastic fumes; so that if a mixture of this kind is put into a close stopp'd bottle, it will almost certainly burst it. The same effect follows upon mixing spirit of salt and spirit of nitre together. In this case, both acids become surprisingly volatile; and much of the liquor will be dissipated in fumes, if the mixture is suffered to stand for any considerable time. Such mixtures ought therefore to be made only at the time they are to be used.

1041
Dissolving vitriolic salts in nitrous or marine acids.

2. If vitriolated tartar is dissolved in an equal quantity of strong spirit of nitre, by heating them together in a matras, the stronger vitriolic acid will be displaced by the weaker nitrous one, and the liquor, on cooling, will shoot into crystals of nitre. The same thing happens also upon dissolving vitriolated tartar, or Glauber's salt, in spirit of salt. This observation we owe to Monf. Beaumé, and the reason of it has been already explained. See n° 285.

1042
Decomposition of vitriolic salts by solutions of earth, &c. in nitrous or marine acids.

3. If vitriolated tartar, or Glauber's salt, is dissolved in water, and this solution mixed with another consisting of calcareous earth, silver, mercury, lead, or tin, dissolved in the nitrous or marine acids, the vitriolic acid will leave the fixed alkali with which it was combined, and, uniting with the calcareous earth or metal, fall with it to the bottom of the vessel. This decomposition takes place only when the vitriolic acid meets with such bodies as it cannot easily dissolve into a liquid, such as those we have just now mentioned; for though vitriolated tartar is mixed with a solution of iron, copper, &c. in the nitrous or marine acids, no decomposition takes place. The case is not altered, whatever acid is made use of; for the marine acid will effectually separate silver, mercury, or lead, from the vitriolic or nitrous acids.

1043
By lime-water.

4. According to Dr Lewis, if a solution of vitriolated tartar is dropt into lime-water, the acid will unite with the lime, and precipitate with it in an indissoluble selenite, the alkali remaining in the water in a pure and caustic state.

1044
Of green vitriol by saccharum saturni.

5. If green vitriol is mixed with any solution containing substances which cannot be dissolved into a liquid by the vitriolic acid, the vitriol will be immediately decomposed, and the liquor will become a solution of iron only. Thus, if green vitriol is mixed with a solution of saccharum saturni, the vitriolic acid immediately quits the iron for the lead, and falls to the

bottom with the latter, leaving the vegetable acid of the saccharum saturni to combine with the iron.

Phenomena from mixtures of Acid, &c. Salts.

6. If solution of tin in aqua regia is mixed with solution of saccharum saturni, the marine acid quits the tin for the lead contained in the saccharum; at the same time, the acetous acid, which was combined with the lead, is unable to dissolve the tin which was before kept suspended by the marine acid. Hence, both the saccharum saturni, and solution of tin, are very effectually decomposed, and the mixture becomes entirely useless. Dyers and callico-printers ought to attend to this, who are very apt to mix these two solutions together; and no doubt many of the faults of colours dyed or printed in particular places, arise from injudicious mixtures of a similar kind. See DYEING.

1045
Of solution of tin by saccharum saturni.

7. If mild volatile alkali, that is, such as remains in a concrete form, by being united with a large quantity of fixed air, is poured into a solution of chalk in the nitrous or marine acids, the earth will be precipitated, and a true sal ammoniac formed. If the whole is evaporated to dryness, and a considerable heat applied, the acid will again part with the alkali, and combine with the chalk. Thus, in the purification of volatile alkalies by means of spirit of salt, the same quantity of acid may be made to serve a number of times. This will not hold in volatile spirits prepared with quicklime.

1046
Of calcareous solutions by mild volatile alkali.

8. If equal parts of sal ammoniac and corrosive sublimate mercury are mixed together and sublimed, they unite in such a manner as never to be separable from one another without decomposition. The compound is called *sal alembroth*; which is said to be a very powerful solvent of metallic substances, gold itself not excepted. Its powers in this, or any other respect, are at present but little known. By repeated sublimations, it is said this salt becomes entirely fluid, and refuses to arise in the strongest heat.

1047
Sal alembroth.

9. If vitriolic acid is poured upon any salt difficult of solution in water, it becomes then very easily soluble. By this means, vitriolated tartar, or cream of tartar, may be dissolved in a very small quantity of water.

1048
Solution of salts promoted by vitriolic acid.

SECT. II. *Earths.*

THE general divisions and characters of these substances we have already given; and most of their combinations with saline substances have been mentioned, excepting only those of the terra ponderosa; a substance whose properties have been but lately inquired into, and are not yet sufficiently investigated. In this section, therefore, we have to take notice only of their various combinations with one another, with inflammable, or metallic substances, &c. As they do not, however, act upon one another till subjected to a vitrifying heat, the changes then induced upon them come more properly to be treated of under the article GLASS. Upon metallic and inflammable substances (sulphur alone excepted), they have very little effect; and therefore what relates to these combinations shall be taken notice of in the following sections. We shall here confine ourselves to some remarkable alterations in the nature of particular earths by combination with certain substances, and to the phosphoric quality of others.

§ 1. The TERRA PONDEROSA.

This earth is of the true calcareous kind, and capable of being converted into a very acrid lime; but in other respects is very different. It is most commonly met with in the veins of rocks, united with the vitriolic acid in a mass somewhat resembling gypsum, but much heavier and more opaque; and from the great weight of this substance the earth itself has its name, though when freed from the acid it is by no means remarkable for this property. Its properties were first taken notice of by the foreign chemists; but they have been more accurately investigated by Dr Withering, who has published his observations in the 74th volume of the Philosophical Transactions. His experiments were not made on the gypseous substance above mentioned; but on a combination of the earth with fixed air, which is much more uncommon, and like the other possesses a very considerable degree of specific gravity. Both these combinations have the general name of *spathum ponderosum*, or *ponderous spar*; the former being also called *baroselenite*, &c.

The spar used by Dr Withering was got out of a lead mine at Alston moor in Cumberland. Its appearance was not unlike that of a lump of alum; but on closer inspection it appeared to be composed of slender spiculae in close contact, more or less diverging, and so soft that it might be cut by a knife; its specific gravity from 4.300 to 4.338. It effervesced with acids, and melted, though not very readily, under the blow-pipe. In a common fire it lost its transparency; and on being urged with a stronger heat in a melting furnace, it adhered to the crucible, and showed signs of fusion; but did not appear to have lost any of its fixed air, either by diminution in weight, becoming caustic, or losing its power of effervescing with acids.

Five hundred grains of this spar, by solution in muriatic acid, lost 104 grains in weight, and left an insoluble residuum of three grains. In another experiment, 100 grains of spar lost 21; and there remained only 0.6 of a grain of insoluble matter.

On dissolving another hundred grains in dilute muriatic acid, 25 ounce-measures of air were obtained, which by proper trials appeared to be pure aerial acid; and, on precipitating the solution with mineral alkali, 100 grains of earth were again obtained; but on dissolving the precipitate in fresh muriatic acid, only 20 ounce-measures of air were produced.

Mild vegetable alkali precipitated a saturated solution of this spar in marine acid, with the escape of a quantity of fixed air; and the same effect took place on the addition of fossil alkali; but with caustic alkalis there was no appearance of effervescence, though a precipitate likewise fell.

Fifty parts of spar, dissolved in marine acid, lost $10\frac{1}{2}$; and with caustic vegetable alkali, a precipitate weighing $45\frac{1}{2}$ was obtained. Phlogisticated alkali precipitated the whole of the earth, as appeared by the addition of mild fixed alkali afterwards, which occasioned no farther precipitation.

Part of the precipitate thrown down by the mild alkali was exposed to a strong heat in a crucible, and then put into water. The liquid was instantly converted into a very acrid lime-water, which had the following remarkable properties: 1. The smallest portion of vitriolic acid, added to this water, occasioned an

immediate and copious precipitation, which appeared even after the liquid was diluted with 200 times its bulk of pure water. 2. A single drop let fall into a solution of Glauber's salt, vitriolated tartar, alum, vitriolic ammoniac, Epsom salt, or selenite, occasioned an immediate and copious precipitate in all of them: the reason of which was the superior attraction of the ponderous earth for the acid of these salts, which forming with it an indissoluble concrete, instantly fell to the bottom.

The precipitate thrown down by the caustic vegetable alkali was put into water, but exhibited no such appearances as the other: even the mixture was boiled; nor had it any acrimonious taste. On adding the three mineral acids to separate portions of the precipitate itself, neither effervescence, nor any sign of solution, appeared. After standing an hour, water was added, and the acids were suffered to remain another hour on the powder; but on decanting them afterwards, and adding fossil alkali to the point of saturation, no precipitate appeared.

The precipitate thrown down by the phlogisticated alkali, mixed with nitre and borax, and melted with a blow-pipe on charcoal, formed a black glass; on flint-glass, a white one; and on a tobacco-pipe, a yellowish white one. Another portion, melted with soap and borax in a crucible, formed a black glass.

The small quantity of insoluble residuum formerly mentioned, appeared to be the combination of ponderous earth with vitriolic acid, called *heavy gypsum*, *marmor metallicum*, *baroselenite*, &c.

From these experiments the Doctor concludes, that 100 parts of this spar contain 78.6 of pure ponderous earth, $\frac{6}{100}$ of a grain of marmor metallicum, and 20.8 grains of fixed air. 2. The quantity of mild alkali necessary to saturate any given portion of acid, contains a greater quantity of fixed air than can be absorbed by that quantity of terra ponderosa which the acid is able to dissolve. 3. The terra ponderosa, when precipitated by means of a mild alkali, readily burns to lime; and this lime-water proves a very nice test of the presence of vitriolic acid. 4. In its native state the terra ponderosa will not burn to lime; when urged with a strong fire, it melts and unites with the crucible, without becoming caustic; nor can it be made to part with its fixed air by any addition of phlogiston. He conjectures, therefore, that as caustic lime cannot unite to fixed air without moisture, and as this spar seems to contain no water in its composition, it is the want of water which prevents the fixed air assuming its elastic aerial state. "This supposition (says he) becomes still more probable, if we observe, that when the solution of the spar in an acid is precipitated by a mild alkali, some water enters into the composition of the precipitate; for it has the same weight as before it was dissolved, and yet produces only 20 ounce-measures of fixed air, while the native spar contains 25 of the same measures: so that there is an addition of weight equal to five ounce-measures of air, or three one-half grains, to be accounted for; and this can only arise from the water. 5. The precipitate formed by the caustic alkali, taking some of the latter down with it, forms a substance neither soluble in acids nor water. This insoluble compound is also formed by adding the lime-water already

ready mentioned, to a solution of caustic vegetable, or fossil fixed alkali, but not with volatile alkali. 6. Fixed vegetable as well as mineral alkali, and even volatile alkalies, whether mild or caustic, are capable of separating terra ponderosa from any other acid excepting the vitriolic; but from it neither mild nor caustic alkalies are capable of separating this earth, excepting the vegetable fixed alkali, which will partly do it by an intense heat in the dry way. 7. This earth affords an excellent method of purifying the nitrous and marine acids from any portion of the vitriolic; for the attraction between terra ponderosa and this acid is so strong, that the least portion of the latter will be instantly detected by the lime-water above mentioned. The vitriolic acid, Dr Withering observes, is commonly adulterated with a white powder, which discovers itself by turning the liquor milky when the acid is diluted with water; and this powder he finds to be gypsum, from the following properties:

1. By repeated boiling in water, six grains and a half were reduced to two. 2. By gentle evaporation this solution afforded five grains of crystals as hard and tasteless as selenite. 3. A precipitate was formed by mild fossil alkali on adding it to a solution of these crystals in water. 4. On exposing this powder to a pretty strong heat, and then putting it into water, the latter became acrid, and acquired the taste of lime-water. 5. The insoluble part suffered no change by boiling in nitrous acid: one half of it mixed with borax, and exposed to the blow-pipe upon charcoal, melted into glass; the other half, mixed with borax, and exposed to the blow-pipe upon charcoal, did the same; whence it appears, says our author, that the greater part of this substance was calx vitriolate or selenite; the remainder a vitrifiable earth. He had before found, that the heavy gypsum, or marmor metallicum, would dissolve in concentrated vitriolic acid, but always separated upon the addition of water; and from his experiments it now appears that selenite does the same.

cum.

1061
Description
of a kind
found near
Edinburgh

Dr Withering next proceeds to give a set of experiments on the heavy gypsum, marmor metallicum of Cronstadt, or the Baroselenite of others, already mentioned. The specimens he obtained were from Kilpatrick hills near Glasgow, and a sort with smaller crystals found among the iron ore about Ketley in Shropshire, and in the lead-mines at Alston-Moor. He describes it as white, nearly transparent, but without the property of double refraction; composed of laminæ of rhomboidal crystals, and decrepitating in the fire; the specific gravity from 4.402 to 4.440. The specimens we have seen differ considerably from this description, being composed, to appearance, of thin laminæ; which all together form a very opaque white mass, which has not the least transparency unless split excessively thin. They are found about three miles to the southwest of Edinburgh, near Pentland hills, and likewise betwixt Edinburgh and Leith. In the former place they lie in small veins of a rock consisting of a kind of iron stone, and so closely adhering to it, that it would seem either that the stone is converted into the spathum ponderosum, or the latter into the stone. It is therefore often intermixed with the rock so intimately, that it is impossible to separate them perfectly from each other.

VOL. IV. Part II.

Dr Withering having exposed 100 grains of the marmor metallicum to a red heat for an hour, in a black crucible, found that it had lost five grains of its weight; but as a sulphureous smell was perceptible, he suspected that a decomposition had taken place, and therefore exposed another portion to a similar heat in a tobacco-pipe, which had no smell of sulphur, nor was it diminished in weight. It melted with borax into a white opaque glass, but was barely fusible by itself under the blow pipe. It did not seem to dissolve in water, nor in any of the acids, except the vitriolic, when by long boiling it had become very concentrated and almost red hot. It then appeared perfectly dissolved; but separated again unchanged on the addition of water. On exposing the vitriolic solution to the atmosphere for some days, beautiful radiated crystals were formed in it.

On adding a solution of mild vegetable alkali to this vitriolic solution, a precipitate appeared; but it consisted of marmor metallicum unchanged. An ounce of it in fine powder was then fused with two of salt of tartar until it ran thin, when six drachms of a residuum insoluble in water were left. On the addition of nitrous acid, only 52 grains were left, which appeared to be marmor metallicum unchanged. On saturating the alkaline solution with distilled vinegar, and washing the precipitate, the liquor was found to contain terra foliata tartar, formed by the union of the acetous acid with part of the alkali; and of vitriolated tartar, formed by that of the alkali with the native acid of the marmor metallicum.

The salt formed by the nitrous acid shot readily into beautiful permanent crystals of a rough bitterish taste. Some of the salt deflagrated with nitre and charcoal, left by washing the terra ponderosa very white, capable of being burnt into lime, and again forming an insoluble compound with vitriolic acid. An hundred grains of acrated terra ponderosa, dissolved in marine acid, and precipitated by the vitriolic, were augmented 17 grains in weight. Hence it appears,

1. That the marmor metallicum is composed of vitriolic acid and terra ponderosa. 2. That this compound has very little solubility in water. 3. That it can only be dissolved in highly concentrated oil of vitriol, from which it separates unchanged on the addition of water. 4. That it cannot be decomposed in the moist way, by mild fixed alkali, though it may be so in the dry. 5. That it may be decomposed by the union of inflammable matter to its acid, by which sulphur is formed, though the acid cannot be dissipated by mere heat. 6. An hundred parts of this substance contain 32.8 of pure vitriolic acid, and 67.2 of terra ponderosa. The marmor metallicum, our author remarks, may possibly be useful in some cases where a powerful flux is wanted; for having mixed some of it with the black flux, and given the mixture a strong heat in a crucible, it ran entirely through the pores of the vessel.

Dr Withering describes two other kinds of this substance, known by the name of *cauk*, and found in the mines of Derbyshire, and other places. These differ from the other only in containing a small proportion of iron. On the whole, he concludes, that "the terra ponderosa seems to lay claim to a middle place betwixt the earths and metallic calces. Like the for-

mer it cannot be reduced to a metallic form, though like the latter it may be precipitated by phlogistified alkali. In many of its properties it much resembles the calx of lead, and in others the common calcareous earth. Its most remarkable properties are its decomposing the vitriolic neutral salts, and forming, with the nitrous and marine acids, crystals which do not deliquesce.

§ 2. *Transmutation of FLINTS into an EARTH soluble in Acids.*

1069
Solution of
flint.

THIS is effected by mixing powdered flints with alkaline salt, and melting the mixture by a strong fire. The melted mass deliquesces in the air, like alkaline salts; and if the flint is then precipitated, it becomes soluble in acids, which it entirely resisted before.

In this process the alkali, by its union with the flint, is deprived of its fixed air, and becomes caustic. To this causticity its solvent power is owing; and therefore the flint may be precipitated from the alkali, not only by acids, but by any substance capable of furnishing fixed air; such as magnesia alba or volatile alkali. The precipitate in both cases proves the same; but the nature of it hath not hitherto been determined. Some have conjectured that the vitriolic acid existed in the flint; in which case, the alkali made use of in this process ought to be partly converted into vitriolated tartar.

1070
Solubility
of this earth
denied by
Mr Berg-
man.

The above process is delivered on the authority of former chemists; but Mr Bergman, who has published a dissertation on this subject, asserts that it cannot be dissolved except by the fluor acid. The vitriolic, nitrous, or marine acids, have no effect upon it, even when newly precipitated from the liquor of flints washed and still wet, and though a thousand parts of acid be added to one of the earth, and boiled upon it for an hour: but when three parts of alkaline salt are melted in a crucible with one of quartz, the salt dissolves at the same time about seven hundredth parts of its own weight of the clay which composes the crucible; and the solubility of this has given occasion to the mistake above mentioned. If the fusion be performed in an iron vessel, no soluble part will be obtained, excepting the very small portion of clay which the quartz contains; and when this is once exhausted by an acid, no more can be procured by any number of fusions with alkali.

1071
Reason of
the mistake
of former
chemists.

1072
Crystals of
flint artifi-
cially form-
ed by Mr
Bergman.

The fluor acid, he observes, is never obtained entirely free from siliceous earth, and consequently its power as a menstruum must be weakened in proportion to the quantity it contains. In order to observe its solvent power, however, our author, in the year 1772, put some quartz, very finely powdered, into a bottle containing $\frac{1}{8}$ of a kanne of fluor acid. The bottle was then slightly corked, and set by in the corner of a room. Two years afterwards it was examined; and on pouring out the liquor there were found concreted at the bottom of the vessel, besides innumerable small prismatic spiculæ, 13 crystals of the size of small peas, but mostly of an irregular form. Some of these resembled cubes, whose angles were all truncated, such as are often found in the cavities of flints. These were perfect siliceous crystals, and very hard, but not comparable with quartz, though they agreed with it

in essential properties. "Possibly (says he) the length of a century may be necessary for them to acquire, by exsiccation, a sufficient degree of hardness. The bottom itself, as far as the liquor had reached, was found covered with a very thin siliceous pellicle, which was scarcely visible, but separated on breaking the bottle. It was extremely pellucid, flexible, and showed prismatic colours. These phenomena show, that much siliceous matter is dissolved and suspended" (in the fluor acid). "Whether any of the quartz was taken up in this experiment is uncertain; but it appears probable that little or none was dissolved; since, by the help of heat during the distillation, the acid had previously taken up so much siliceous earth, that upon slow evaporation it was unable to retain it. Hence appears the origin of the crystals and the pellicle; and hence appears the cause which impedes the action of fluor acid upon flint; namely, that the acid obtained in the ordinary way is already saturated with it."

The volatile alkali precipitates siliceous earth most completely from fluor acid: and thus we find, that one part of it is contained in 600 of the acid, diluted to such a degree, that its specific gravity is only 1.064. This precipitate has all the properties of pure flint; but that precipitated either by vegetable or mineral fixed alkali does not afford a pure siliceous earth, but a peculiar kind of triple salt, formed of the earth, fluor acid, and fixed alkali, which dissolves, though with difficulty, in warm water, especially the earth procured by vegetable alkali, but is easily decomposed by lime-water, and lets fall the mineral fluor regenerated.

Fixed alkaline salts attack this earth by boiling, but not unless it be reduced to very fine powder, and newly precipitated from the liquor. Oil of tartar per deliquium takes up about one-sixth of its weight, and the liquor becomes gelatinous on cooling, though at first diluted with 16 times its weight of water. This solution is effected only by the caustic part; for when fully saturated with fixed air, it cannot enter into any union with it. Volatile alkali, even though caustic, has no effect.

The attraction betwixt siliceous earth and fixed alkali is much more remarkable in the dry way; for thus it melts with one half its weight of alkali into an hard, firm, and transparent glass, the aerial acid and water going off in a violent effervescence. In proportion as the alkali is increased, the glass becomes more soft and lax, until at last it dissolves totally in water, as has been already mentioned. The siliceous matter thus precipitated is of a very rare and spongy texture, and so much swelled by water, that its bulk when wet is at least twelve times greater than when dry; nor does it contract more though suffered to remain a long time in the water. Hence it is easy to reduce the liquor of flints to a jelly, by diluting it with four or eight times its weight of water, and adding a sufficient quantity of precipitate; but if an over-proportion of water be used, for instance, 24 times the weight, the liquor will then remain limpid, though we add as much acid as is sufficient for saturating the alkali. The reason of this Mr Bergman supposes to be, that the siliceous particles are removed to such a distance from one another, that they cannot overcome the out heat.

Phosphoric Earths. the friction they must necessarily meet with in their passage downwards through the fluid; but if the liquor be boiled, which at once diminishes its quantity and tenacity, the siliceous matter is instantly separated.

1080
Liquor of flints decomposed by too great a quantity of water, and by fluor acid. Liquor of flints is also decomposed by too great a quantity of water; for by this the efficacy of the menstruum is weakened, and it is also partly saturated by the aerial acid contained in the water. A precipitate also falls when the fluor acid is made use of; the reason of which is the same as the precipitation by other acids: in this case, however, the alkali makes part of the precipitate, as has been already observed; and therefore the matter which falls is fusible before the blow-pipe, and soluble in a sufficient quantity of water.

§ 3. Of PHOSPHORIC Earths.

1081
Bolognian stone. THESE are so called from their property of shining in the dark. The most celebrated and anciently known of this kind is that called the *Bolognian stone*, from Bologna, a city in Italy, near which it is found. The discovery, according to Lemery, was accidentally made by a shoe-maker called *Vincenzo Casciarolo*, who used to make chemical experiments. This man, having been induced to think, from the great weight and lustre of these stones, that they contained silver, gathered some, and calcined them; when carrying them into a dark place, probably by accident, he observed them shining like hot coals.

Mr Margraaff describes the Bolognian stone to be an heavy, soft, friable, and crystallized substance, incapable of effervescence with acids before calcination in contact with burning fuel. These properties seem to indicate this stone to be of a selenitic or gypseous nature.

1082
How rendered luminous. When these stones are to be rendered phosphoric, such of them ought to be chosen as are the cleanest, best crystallized, most friable and heavy; which exfoliate when broken, and which contain no heterogeneous parts. They are to be made red hot in a crucible; and reduced to a very fine powder in a glass-mortar, or upon a porphyry. Being thus reduced to powder, they are to be formed into a paste with mucilage of gum tragacanth, and divided into thin cakes. These are to be dried with a heat, which at last is to be made pretty considerable. An ordinary reverberating furnace is to be filled to three quarters of its height with charcoal, and the fire is to be kindled. Upon this charcoal the flat surfaces of the cakes are to rest, and more charcoal to be placed above them, so as to fill the furnace. The furnace is then to be covered with its dome, the tube of which is to remain open; all the coal is to be consumed, and the furnace is to be left to cool; the cakes are then to be cleansed from the ashes by blowing with bellows upon them. When they have been exposed during some minutes to light, and afterwards carried to a dark place, they will seem to shine like hot coals; particularly if the person observing them has been some time in the dark, or have shut his eyes, that the pupils may be sufficiently expanded. After this calcination through the coals, if the stones be exposed to a stronger calcination, during a full half hour, under a muffle, their phosphoric quality will be rendered stronger.

From attending to the qualities of this stone, and the requisites for making this phosphorus, we are naturally led to think, that the Bolognian phosphorus is no other than a composition of sulphur and quicklime. The stone itself, in its natural state, evidently contains vitriolic acid, from its not effervescing with acids of any kind. This acid cannot be expelled from earthy substances by almost any degree of fire, unless inflammable matter is admitted to it. In this case, part of the acid becomes sulphureous, and flies off; while part is converted into sulphur, and combines with the earth. In the above mentioned process, the inflammable matter is furnished by the coals in contact with which the cakes are calcined, and by the mucilage of gum tragacanth with which the cakes are made up. A true sulphur must therefore be formed by the union of this inflammable matter with the vitriolic acid contained in the stone; and part of this sulphur must remain united to the earth left in a calcareous state, by the dissipation, or conversion into sulphur, of its acid.

1084
All calcareous stones, phosphoric, according to Mr du Fay. In the year 1730, a memoir was published by Mr du Fay; wherein he asserts, that all calcareous stones, whether they contain vitriolic acid or not, are capable of becoming luminous by calcination; with this difference only, that the pure calcareous stones require a stronger, or more frequently repeated, calcination to convert them into phosphorus; whereas those which contain an acid, as selenites, gypsum, spars, &c. become phosphoric by a slighter calcination. On the contrary, Mr Margraaff asserts, that no other stones can be rendered phosphoric but those which are saturated with an acid; that purely calcareous stones, such as marble, chalk, limestone, stalactites, &c. cannot be rendered luminous, till saturated with an acid previously to their calcination.

We have already taken notice, that the compounds formed by uniting calcareous earths with the nitrous and marine acids become a kind of phosphori; the former of which emits light in the dark, after having been exposed to the sun through the day; and the latter becomes luminous by being struck. **1085**
Signior Beccaria's observation. Signior Beccaria found, that this phosphoric quality was capable of being given to almost all substances in nature, metals perhaps excepted. He found that it was widely diffused among animals, and that even his own hand and arm possessed it in a very considerable degree. In the year 1775, a treatise on this kind of phosphori was published by B. Wilson, F. R. S. and member of the Royal Academy at Upsal. **1086**
Mr Wilson's experiments. In this treatise he shows, that oyster-shells, by calcination, acquire the phosphoric quality in a very great degree, either when combined with the nitrous acid or without it.

The first experiment made by our author was the pouring some aquafortis, previously impregnated with copper, on a quantity of calcined oyster-shells, so as to form them into a kind of paste; he put this paste into a crucible, which was kept in a pretty hot fire for about 40 minutes. Having taken out the mass, and waited till it was cool, he presented it to the external light. On bringing it back suddenly into the dark, he was surprised with the appearance of a variety of colours like those of the rainbow, but much more vivid. In consequence of this appearance of the prismatic colours,

Vegetable
Earth.

colours, he repeated the experiment in various ways, combining the calcined oyster-shells with different metals and metallic solutions, with the different acids, alkaline and neutral salts, as well as with sulphur, charcoal, and other inflammable substances; and by all of these he produced phosphori, which emitted variously coloured light.

1087
Surprising
phosphoric
quality of
oyster-
shells.

What is more remarkable, he found that oyster-shells possessed the phosphoric quality in a surprising degree; and for this purpose nothing more was requisite than putting them into a good sea-coal fire, and keeping them there for some time. On scaling off the internal yellowish surface of each shell, they become excellent phosphori, and exhibit the most vivid and beautiful colours. As we know that neither the vitriolic nor any other acid is contained in oyster-shells, we cannot as yet say any thing satisfactory concerning the nature of this phosphorus.

§ 4. Of the VEGETABLE Earth.

1088
Dr Lewis's
opinion

THIS is produced from vegetables by burning, and, when perfectly pure, by lixiviating the ashes with water, to extract the salt; and then repeatedly calcining them, to burn out all the inflammable matter; and is perhaps the same from whatever substance it is obtained: in this state, according to Dr Lewis, it is of the same nature with magnesia. In the state, however, in which this earth is procurable by simply burning the plant, and lixiviating the ashes, it is considerably different, according to the different plants from which it is obtained. The ashes of mugwort, small centaury, chervil, and dill, are of a brownish grey; goat's beard and lungwort afford white ashes; those of fanicle are whitish; those of Roman wormwood of a greenish grey; those of rue, agrimony, saxifrage, brown; those of tansey, of a dusky green; those of dodder, of a fine green; eyebright, southern-wood, common wormwood, and scabious, afford them grey; scurvy-grass, of a whitish grey; hyssop, yarrow, and fowbane, of a dusky grey; melilot, and oak-leaves, as also plantain, colts-foot, pine-tops, and fumitory, of a dusky brown; penny-royal, of a pale brown, with some spots of white; elder-flowers, sage, and mother of thyme, afford yellow ashes; those of strawberry-leaves are of a pale brimstone colour; those of cat-mint, of a dusky red; of prunella, brick-coloured; of honey-suckle, blue; of fern, blackish; and those of St John's-wort, feverfew, origanum, and pimpinell, all of a deep black. The only use to which this kind of earth has yet been put, is that of glass-making and manure.

1089
Mr Gmelin's
experiments.

SECT. III. Of Metallic Substances.

§ 1. GOLD.

THIS metal is reckoned of all others the most perfect and indestructible. When in its greatest purity, it has very little elasticity, is not sonorous, its colour is yellow, it is exceedingly soft and flexible, and is more ductile than any other metal whatever. (See *GOLD Leaf*, and *WIRE-DRAWING*.) Of all bodies it is the most ponderous, except platina; its gravity being to that of water, according to Dr Lewis, as 19,280,

or 19,290, to one. For its fusion it requires a low degree of white heat, somewhat greater than that in which silver melts. Whilst fluid, it appears of a bluish green colour; when cold, its surface looks smooth, bright, and considerably concave: it seems to expand more in the act of fusion, and to shrink more in its return to solidity, than any of the other metals; whence the greater concavity of its surface. Before fusion it expands the least of all metals, except iron. By sudden cooling it becomes, as well as other metals, brittle; which effect has been erroneously attributed to the contact of fuel during fusion.

Gold amalgamates very readily with mercury, and mingles in fusion with all the metals. It is remarkably disposed to unite with iron; of which it dissolves many times its own weight, in a heat not much greater than that in which gold itself melts; the mixture is of a silver colour, very brittle and hard. All the metals, except copper, debase the colour of gold; and, if their quantity is nearly equal to that of the gold, almost entirely conceal it.

The malleability of gold is impaired by all the metals, but less by copper and silver than any others. Tin has had a remarkably bad character in this respect; and it has been a received opinion among metallurgists, that the smallest quantity of this metal entirely destroys the ductility of gold; and Dr Lewis tells us, that "the most minute portion of tin or lead, and even the vapours which rise from them in the fire, though not sufficient to add to the gold any weight sensible on the tenderest balance, make it so brittle, that it flies to pieces under the hammer." On so respectable an authority, this continued to be believed as an undoubted fact, until, in the year 1784, a paper appeared in the *Philosophical Transactions* by Mr Alchorne of the mint; in which it was clearly disproved by the following experiments:

1. Sixty Troy grains of pure tin were put into 12 ounces of pure gold in fusion; after which the mixture was cast into a mould of sand, producing a flat bar an inch wide, and an eighth of an inch thick. The bar appeared sound and good, suffered flattening under the hammer, drawing several times between a pair of steel-rollers, and cutting into circular pieces of near an inch diameter, which bore stamping in the money-press by the usual stroke, without showing the least brittleness, or rather with much the same ductility as pure gold.

2. With 90 grains of tin the bar was scarce distinguishable from the former.

3. With 120 grains it was rather paler and harder; and on drawing between the rollers the edges were a little disposed to crack.

4. With 140 grains, the paleness, hardness, and disposition to crack, were evidently increased; nevertheless it bore every other operation, even stamping under the press, without any apparent injury.

5. With an ounce of tin the bar was lead-coloured and brittle, splitting into several pieces on the first passing between the rollers.

6. A small crucible filled with standard gold $\frac{1}{2}$ fine, was placed in a larger one, having in it an ounce of melted tin. The whole was covered with a large crucible inverted, in order to direct the fumes of the tin downward upon the gold. The metals were kept in fusion

^{Gold.} fusion for half an hour, during which time a full quarter of the tin was calcined; yet the gold remained altogether unchanged.

7. The mixture of gold and tin produced in exp. 1. was melted a second time in a stronger fire than at first, and kept in fusion for half an hour; during which time six grains of weight were lost, but the gold remained equally perfect as before.

¹⁰⁹⁴
Nor by the
addition of
copper.

8. and 9. The mixtures of exp. 2. and 4. viz. 90 and 140 grains to 12 ounces of gold, were re-melted separately, and an ounce of copper added to each. On being cast as usual, they bore all the operations of manufacturing as before, though sensibly harder. The last cracked at the edges as it had done without the copper, but bore cutting rather better than in its former state.

10. and 11. A quarter of an ounce of the last mixture, being tin 140 grains, and copper an ounce, and gold 12 ounces, with as much of the bar from experiment 3. consisting of 140 grains of tin to 12 ounces of gold, were each melted by a jeweller in a common sea-coal fire, into small buttons, without any loss of weight. These buttons were afterwards forged into small bars, nealing them often with the flame of a lamp, and afterwards drawn each about twenty times through the apertures of a steel plate, into fine wire, with as much ease as coarse gold commonly passes the like operation.

12. Sixty grains of tin were added to 12 ounces of standard gold $\frac{1}{12}$ fine; and the compound passed every one of the operations already described, without showing the least alteration from the tin.

Several other trials were made with different mixtures of copper, tin, and silver, with gold, even as low as two ounces and a half of copper, with half an ounce of tin, to twelve ounces of gold; all of which bore hammering and flattening by rollers to the thinness of stiff paper, and afterwards working into watch-cases, cane-heads, &c. with great ease. They grew more hard and harsh indeed in proportion to the quantity of alloy; but not one of them had the appearance of what workmen call brittle gold. Mr Alchorne therefore is of opinion, that when brittleness has been occasioned by the addition of tin to gold, the former has been adulterated with arsenic; as he has found, that by adding 12 grains of regulus of arsenic to as many ounces of fine gold, the compound has been rendered altogether unmalleable.

When gold is struck during a certain time by a hammer, or when violently compressed, as by the wire-drawers, it becomes more hard, elastic, and less ductile; so that it is apt to be cracked and torn. Its ductility is, however, restored by the same means used with other metals, namely, heating it red hot, and letting it cool slowly. This is called *annealing* metals; and gold seems to be more affected by this operation than any other metal. The tenacity of the parts of gold is also very surprising; for a wire of $\frac{1}{10}$ of an inch in diameter will support a weight of 500 pounds.

¹⁰⁹⁶
Surprising
tenacity of
its parts.

Gold is unalterable by air or water. It never contracts rust like other metals. The action of the fiercest furnace-fires occasions no alteration in it. Kunkel kept gold in a glass-house furnace for a month, and Boyle kept some exposed to a great heat for a still longer time, without the loss of a single grain.

¹⁰⁹⁷
Not liable
to rust.

It is said, however, to be dissipable in the focus of a large burning mirror.

Mr Boyle relates a very curious and extraordinary experiment, which he thought was sufficient to prove the total destructibility of gold. About an eighth part of a grain of powder, communicated by a stranger, was projected upon two drachms of fine gold in fusion, and the matter kept melted for a quarter of an hour. During the fusion, it looked like ordinary gold; except only once, that his assistant observed it to look exactly of the colour of opal. When cold, it was of a dirty colour, and, as it were, overcast with a thin coat, almost like half-vitrified litharge: the bottom of the crucible was overlaid with a vitrified substance, partly yellow, and partly reddish brown; with a few small globules, more like impure silver than gold. The metal was brittle, internally like brass or bell-metal; on the touchstone more like silver than gold: its specific gravity was to that of water only as $15\frac{1}{2}$ to 1. There was no absolute loss of weight. By cupellation, 60 grains of this mass yielded 53 grains of pure gold, with seven grains of a ponderous, fixed, dark-coloured substance.

^{Gold.}

experiments for
the destructibility of
gold.

We have already mentioned, that in certain circumstances gold is soluble in the nitrous and marine acids separately. It is, however, always soluble by the two united, but dissolves slowly even then. The most commodious method of obtaining this solution is, by putting the gold, either in leaves, or granulated, or cut into small thin pieces, into a proper quantity of aquafortis; then adding, by degrees, some powdered sal ammoniac, till the whole of the gold is dissolved. By this means a much smaller quantity of the menstruum proves sufficient, than if the sal ammoniac was previously dissolved in the aquafortis; the conflict, which each addition of the salt raises with the acid, greatly promoting the dissolution. Aquafortis of moderate strength will, in this way, take up about one-third of its weight of gold; whereas an aqua regis, ready prepared from the same aquafortis, will not take up above one-fifth its weight. Common salt answers better for the preparation of the aqua regis than sal ammoniac.

¹⁰⁹⁹
Solution in
aqua regia.

This solution, like all other metallic ones, is corrosive. It gives a violet colour to the fingers, or to any animal matters. If the solution is evaporated and cooled, yellow transparent crystals will be formed; but, if the evaporation is carried too far, the acids with which the gold is combined may be driven from it by heat alone; and the gold will be left in the state of a yellow powder, called *calx of gold*.

¹¹⁰⁰
Properties
of the solution.

Gold may be precipitated from its solution by those substances which commonly precipitate metals, such as alkaline salts and calcareous earths. It may also be precipitated in a fine purple powder, by tin or its solution.

¹¹⁰¹
Gold precipitated
from it.

When fixed alkalies are made use of, the precipitate weighs about one-fourth more than the gold employed. With volatile alkalies also, if they are added in no greater proportion than is sufficient to saturate the acid, the quantity of precipitate proves nearly the same: but if volatile spirit is added in an over-proportion, it redissolves part of the gold which it had before precipitated, and the liquor becomes again considerably yellow. The whole of the precipitate, however,

Gold.

ever, could not be redissolved, either by the mild or caustic alkali; nor did either of these spirits sensibly dissolve or extract any tinge from precipitates of gold which had been thoroughlyedulcorated with boiling water.

All the metallic bodies which dissolve in aqua regia, precipitate gold from it. Mercury and copper throw down the gold in its bright metalline form; the others, in that of a calx or powder, which has no metallic aspect. Vitriol of iron, though it precipitates gold, yet has no effect upon any other metal; hence it affords an easy method of separating gold from all other metals. The precipitation with tin succeeds certainly only when the metal in substance is used, and the solution of gold largely diluted with water. It is observable, that though the gold is precipitated from the diluted solution by tin, yet, if the whole is suffered to stand till the water has in a great measure exhaled, the gold is taken up afresh, and only a white calx of tin remains.

tion.

Gold precipitated from its solution in aqua regia explodes by heat with much greater violence than any other substance in nature. This property was known in the 15th century; but whether the ancient alchemists knew any thing of it or not, is a matter of uncertainty. Basil Valentine first gave any distinct account of it. He directs the gold to be dissolved in aqua regia made with sal ammoniac, and then precipitated by vegetable fixed alkali, to be twelve times washed with water, and lastly dried in the open air, where the sun's rays cannot reach it. He forbids it to be dried over a fire, as it explodes with a gentle heat, and flies off with inconceivable violence.

Succeeding chemists have performed this operation with some little differences; but the necessity of employing volatile alkali was but little regarded till the beginning of the present century.

site for the
explosion.

The calx of gold is always somewhat increased in weight by being converted into aurum fulminans; but authors are not agreed about the quantity of augmentation. Becher makes it heavier by one-fifth part; Lemery by one fourth; and Juncker by one-fourth. All agree, however, that it explodes with a violence almost inconceivable. Crollius relates, that 20 grains of this powder explodes with more force than half a pound of gunpowder, and exerts its force downwards, though M. Teykmeyer frequently showed in his lectures that it would throw a florin upwards above six ells. A great number of experiments were made before the Royal Society at London, in order to determine the comparative forces of these two powders. Equal parts of gunpowder and aurum fulminans were included in iron globes placed among burning coals; those which contained the former burst with great violence, but the globes containing the aurum fulminans remained perfectly silent. But though no explosion takes place in close vessels, the utmost caution is necessary in managing this substance in the open air, especially when it is subjected to friction, or to a slight degree of heat; for such is the nature of the calx we speak of, that it is not necessary, in order to cause it explode, to touch it with an ignited substance, or to make it red-hot. The heat requisite for this purpose is, according to Dr Lewis, intermediate between that of boiling water and the heat which makes metals of

an obscure red. With friction, however, it seems still more dangerous; for in this case it explodes with what we should think scarce sufficient to communicate any degree of heat whatever. Orschal relates, that this powder ground in a jasper mortar, exploded with such violence as to burst the vessel in a thousand pieces; Dr Lewis gives an instance of a similar kind in England; and Dr Birch tells us of doors and windows torn to pieces by the violence of this explosive matter. Mr Macquer relates the following accident to which he was witness. "A young man, who worked in a laboratory, had put a drachm of fulminating gold into a bottle, and had neglected to wipe the inner surface of the neck of the bottle, to which some of the powder adhered. When he endeavoured to close the bottle, by turning round the glass stopper, the friction occasioned an explosion of part of the powder. By this the young man was thrown some steps backward, his face and hands wounded by the fragments of the bottle, and his eyes put out; yet, notwithstanding this violent explosion, the whole drachm of fulminating gold certainly did not take fire, as much of it was afterwards found scattered about the laboratory."

It has already been mentioned, that some imagine the force of this explosion to be directed downwards; but Dr Lewis is of opinion that it is equally directed every way. Certain it is, that the quantity of from 10 to 12 grains of aurum fulminans, exploded on a metalline plate, lacerates it; a smaller quantity forms a cavity, and a still smaller only scratches the surface; effects which are never produced by gunpowder in ever so large a quantity. A weight laid upon the powder is thrown upwards in the moment of explosion. If it be of silver or copper, this weight is marked with a yellowish spot, as the supports will also be, if made of either of these metals. A large grain, says Mr Bergman, brought near to the side of the flame of a candle, blows it out with great noise; and a few ounces exploding together by incautious drying, has been known to shatter the doors and windows of the apartment: hence it is evident, that aurum fulminans exerts its force in all directions; yet it cannot be denied, that it strikes bodies with which it is in contact more violently than those which are at a small distance, though in its vicinity: thus, if a small portion of it explodes in a paper box, it lacerates only the bottom, unless the top be pressed down close; in which case it perforates both the top and bottom. When carefully and gradually exploded in a glass phial or a paper box, it leaves a purple foot, in which are found many particles of shining gold; and if the quantity exploded be large, several grains remain totally unchanged, as it is only the lowermost stratum that is inflamed.

Aurum fulminans, when moist, does not explode at all; but as it dries, the grains go off in succession like the decrepitation of common salt.—In glass vessels closed, or with their mouths immersed in water, it explodes, but with a very weak report. An elastic vapour, in the quantity of seven inches, from half a drachm of the powder, broke forth in the moment of explosion, which, by our author's account, seems to be phlogisticated air. In metallic vessels sufficiently strong, the gold is silently reduced when they are perfectly

Gold. feely found; but if they have any very small chinks in them, the vapour makes its way through them with a hissing noise.

1115 Cause of this explosion attributed to a saline principle. The cause of this extraordinary explosive force of gold has been attributed chiefly to a saline principle, viz. the combination of nitrous acid with volatile alkali; and this opinion has been supported by an assertion, that the fulminating property is destroyed by treating the calx with vitriolic acid or with fixed alkali; the former expelling the nitrous acid, and the latter disengaging the volatile alkali.—Mr Bergman allows, that fixed alkali destroys the fulminating property; but affirms, that it acts only by separating the particles when the two are triturated together; and this might be done by many other substances as well as fixed alkali: but when the alkali, instead of being triturated in the dry way with the calx, was boiled in water along with it, the explosion not only took place, but was much more violent than usual. It must be observed, however, that heat alone destroys the fulminating property of this calx; and therefore, if the alkaline solution be made too strong, the additional heat which it then becomes capable of sustaining, is sufficient to deprive the calx of its fulminating property. The case is the same with the vitriolic acid; for this has no effect upon the calx, either by digestion in its concentrated state, or by boiling in its diluted state. If it be boiled in its concentrated state indeed with the fulminating calx, the heat conceived by the acid is sufficient to destroy the fulminating property of the former; and in like manner, unless the calx be in some measure destroyed, or reduced to its metallic state, it can never be deprived of its fulminating property.

1116 This opinion shown to be erroneous by Mr Bergman. It was further proved, that the fulminating property did not depend on the presence either of nitrous or marine acids, for it can be made without them. A calx of gold, not fulminating, dissolved in vitriolic acid, and precipitated by caustic volatile alkali, had acquired this property. A solution of the same calx in nitrous acid, let fall a precipitate by the addition of pure water; and this precipitateedulcorated, and digested with volatile alkali, fulminated as if it had been originally precipitated with that alkali. The experiment was repeated on other non-fulminating precipitates with the same success. Left any suspicion, however, should remain, that a small quantity of aqua-regia might still be left, which, by combining with the volatile alkali, would make a proportionable quantity of nitrum flammans, the precipitate was digested 24 hours in vitriolic acid, then washed in pure water, and immersed in aqueous and spirituous solutions of alkali, both mild and caustic; but the event was the same. Lastly, an inert calx of gold may always be made to fulminate by digesting it with volatile alkali; nor can this property be communicated to it by any means without the use of this alkali.

1117 Aurum fulminans can be made without nitrous or marine acids. It has been supposed by some very eminent chemists, among whom we may number Dr Black, that fixed air is the cause of the fulmination of gold: but it is evident that this cannot be the case; because, 1. Gold fulminates as well when precipitated by the caustic volatile alkali, as by that which contains fixed air. 2. This metal does not combine, during precipitation, with fixed air. 3. Gold, when precipitated by mild

1118 Fixed air not the cause of the explosion. fixed alkali, does not fulminate, unless the menstruum contain volatile alkali.

The fulminating calx of gold may be prepared either with a compound aqua-regia of pure nitrous and marine acids; of pure nitrous acid and sal ammoniac; or of a compound of alum, nitre, and sea-salt. When this kind of liquor is made use of, the acid of the alum expels the other two, and thus forms an aqua-regia. This was formerly called *menstruum sine strepitu*. By whatever method the gold is dissolved, it always affords a yellow calx with alkalies, but the volatile alkali most readily throws down the metal. Dephlogisticated spirit of salt very readily dissolves gold, and produces a fulminating precipitate as well as aqua-regia.

We shall conclude this account of aurum fulminans with an abstract of Mr Bergman's theory of the explosion.—He observes, that volatile alkali contains phlogiston; an undoubted proof of which is given by Dr Priestley, by converting alkaline into phlogisticated air. This phlogiston, says he, may be separated by means of a superior attraction; so that the volatile alkali is decomposed, and the residuum dissipated in form of an elastic fluid, altogether similar to that which is extricated during the fulmination: the source then from whence the elastic fluid is derived must be obvious; and it only remains to examine the medium by which the volatile alkali is dephlogisticated.

“ In those metals which are called *perfect*, so great is the firmness of texture, and so close the connection of the earthy principle with the phlogiston, that by means of fire alone these principles cannot be disunited: but when dissolved by acid menstrua, they must necessarily lose a portion of their phlogiston; and therefore, when afterwards precipitated by alkalies which cannot supply the loss, they fall down in a calcined state, though they attract phlogiston so strongly, that they can be reduced to a metallic state, merely by an intense heat penetrating the vessels. It may therefore be laid down as a fundamental position, that gold is calcined by solution.

“ Let us now consider the consequence of exposing the powder consisting of calx of gold and volatile alkali intimately united, to an heat gradually increased. The calx which is united with the volatile alkali, by the assistance of a gentle heat, seizes its phlogiston; and when this is taken away, the residuum of the salt is instantaneously expanded into the form of an elastic fluid, which is performed with so much violence, that the air must yield a very acute sound.”

Our author proceeds to explain this phenomenon upon the principles assumed by him and Mr Scheele, of heat being a composition of light, and the phlogiston or principle of inflammability; but as this hypothesis is by no means satisfactory, we shall omit his reasoning founded upon it; That the volatile alkali, however, is really capable of producing a flash is easily proved, because it exhibits one when thrown into a hot crucible. A single cubic inch of gun-powder generates about 244 of elastic fluid; but the same quantity of aurum fulminans yields at least four times as much; and hence we may easily understand the difference in their explosive force.

“ That careful calcination should destroy the fulmi-
ni-”

Gold.

1119 Menstruum sine strepitu.

1120

Mr Bergman's theory of the cause of the explosion.

1121

Volatile alkali the cause of the explosion.

1122

Volatile alkali exhibits a flash when thrown into a hot crucible.

1123

Great quantity of elastic fluid produced by aurum fulminans.

^{Gold.} minating property, is not to be wondered at, as the volatile alkali is the indispensable material cause; but, the peculiar alacrity which it acquires before the explosive force is totally extinguished, depends upon the nature of the materials, and of the operation. Thus the heat, when inferior to that necessary for fulmination, acts upon both the principles of the aurum fulminans, it prepares the metallic calx for a more violent attraction for phlogiston; it also acts upon the phlogiston of the volatile alkali, and loosens its connection; which two circumstances must tend to the union producing the explosion. But this effect has a maximum; and at this period the slightest friction supplies the defect of necessary heat, and produces the fulmination. The calcined gold also seems to collect and fix the matter of heat, though still insufficient by means of its phlogiston, in a certain degree: so that by means of friction, though but very slight, it becomes capable of exerting its force; but when the heating is often repeated without producing its effect, the volatile alkali is by degrees dissipated, and at length so much diminished that the calx becomes inert.

¹¹²⁴ Why slight calcination destroys the fulminating property. "But if aurum fulminans is capable of producing such a prodigious quantity of elastic fluid, how does it happen that it remains mute and inert when reduced in close vessels? Of this the reason may be, that every elastic fluid, in the act of breaking forth, requires a space to expand in; and if this be wanting, it remains fixed. Taking this for granted, a calx of gold cannot be reduced in close vessels either by heat or by the phlogiston of volatile alkali; for in either case it must evolve its elastic fluid, which by supposition it cannot do. Nothing remains to solve this difficulty but the ignition of the surrounding metal; by means of which the calx, in virtue of its superior attraction, seizes the phlogiston of the metal, which that substance here, as well as in other instances, is capable of losing without the eruption or absorption of any fluid whatever."

¹¹²⁵ Why it will not explode in close vessels. Several chemists have asserted, that the calces of copper or silver may be made to fulminate like that of gold. But Mr Bergman informs us, that these experiments never succeeded with him; "so (says he) they have either been silent upon some circumstances necessary in the operation, or perhaps have been deceived by the detonation of nitrum flammans, or some other accidental occurrence. It is not sufficient for the volatile alkali to adhere to the precipitate; for platina thrown down by this alkali retains a portion of it very obstinately, but yet does not fulminate on the exposure to fire.—Besides the presence of volatile alkali, it seems to be necessary that the metallic calx should be reducible by a gentle heat, in order to decompose it; but every explosion is not to be derived from the same causes; nay, in this respect, aurum fulminans, gun-powder, and pulvis fulminans, differ very much, though they agree in several particulars." Of late, however, it has been found that the calx of silver may be made to fulminate in a manner still more extraordinary than that of gold. See the next article.

¹¹²⁶ Mr Bergman's opinion of the fulmination of other calces. If gold is melted with an hepar sulphuris, composed of equal parts of sulphur and fixed alkaline salt, the metal readily unites with it into an uniform mass, capable of dissolution in water without any separation of

N^o 74.

its parts. The solution, besides a nauseous taste from the sulphur, has a peculiar penetrating bitterness, not discoverable in any other metalline solution made by the same means.

Though the compositions of sulphur and alkali seem to unite more intimately with gold than any other metal, their affinity with it is but slight; copper, or iron, added to the matter in fusion, disunite, and precipitate the gold. The metal thus recovered, and purified by the common processes, proves remarkably paler-coloured than at first. In an experiment related by Dr Brandt, in the Swedish Memoirs, the purified gold turned out nearly as pale as silver, without any diminution of weight.

¹¹²⁷ Solution of gold by hepar sulphuris. Gold has been thought to be possessed of many extraordinary virtues as a medicine; which, however, are long ago determined to be only imaginary. It is not indeed very easy to prepare this metal in such a manner that it can be safely taken into the human body. The solution in aqua regia is poisonous; but if any essential oil is poured on this solution, the gold will be separated from the acid, and united to the essential oil; with which, however, it contracts no lasting union, but in a few hours separates in bright yellow film to the sides of the glass. ¹¹²⁸ Medicinal virtues of gold. Vitriolic ether dissolves the gold more readily and perfectly than the common essential oils; and keeps it permanently suspended, the acid liquor underneath appearing colourless. The yellow ethereal solution poured off, and kept for some time in a glass stopp'd with a cork, so that the spirit may slowly exhale, yields long, transparent, prismatic crystals, in shape like those of nitre, and yellow like topaz. What the nature of these crystals is, either as to medicinal effects, or other purposes, is as yet unknown.

Rectified spirit of wine mingles uniformly with the solution of gold made in acids: if the mixture is suffered to stand for some days in a glass slightly covered, the gold is by degrees revived, and arises in bright pellicles to the surface. Groffer inflammable matters, wine, vinegar, solutions of tartar, throw down the gold, in its metalline form, to the bottom. Gold is the only metal which is thus separable from its solution in acids by these substances; and hence gold may be purified by these means from all admixtures, and small proportions of it in liquors readily discovered.

¹¹²⁹ Etherial solution. When the colour of gold is by any means rendered pale, it may be recovered again by melting it with copper, and afterwards separating the copper; or by a mixture of verdigris and sal ammoniac with vitriol or nitre. The colour is also improved by fusion with nitre, injecting sal ammoniac upon it in the fusion, quenching it in urine, or boiling it in a solution of alum. When borax is used as a flux, it is customary to add a little nitre or sal ammoniac, to prevent its being made pale by the borax. Juncker reports, that by melting gold with four times its weight of copper, separating the copper by aquafortis unpurified, then melting the gold with the same quantity of fresh copper, and repeating this process eight or nine times, the gold becomes at length of a deep red colour, which sustains the action of lead, antimony, and aquafortis.

¹¹³⁰ Colour of gold restored.

Silver.

§ 2. SILVER.

1131
Ductility
of silver.

THIS, next to gold, is the most perfect, fixed, and ductile of all the metals. Its specific gravity is to that of water nearly as 11 to 1. A single grain has been drawn into a wire three yards long, and flattened into a plate an inch broad. In common fire it suffers no diminution of its weight; and, kept in the vehement heat of a glass-house for a month, it loses no more than one sixty-fourth. In the focus of a large burning-glass, it smokes for a long while, then contracts a greyish ash on the surface, and at length is totally dissipated.

Silver is somewhat harder and more sonorous than gold, and is fusible with a less degree of heat. The tenacity of its parts also is nearly one half less than that of gold; a silver wire of $\frac{1}{16}$ of an inch diameter being unable to bear more than 270 pounds.

1132
Effects of
sulphur on
it.

Mercury unites very readily with silver-leaf, or with the calx of silver precipitated by copper; but does not touch the calces precipitated by alkaline salts. The vapours of sulphureous solutions stain silver yellow or black. Sulphur, melted with silver, debases its colour to a leaden hue, renders it more easily fusible than before, and makes it flow so thin as to be apt in a little time to penetrate the crucible: in a heat just below fusion, a part of the silver shoots up, all over the surface, into capillary efflorescence. Aquafortis does not act upon silver in this compound; but fixed alkaline salts will absorb the sulphur, and form a hepar sulphuris, which, however, is capable of again dissolving the metal. If the sulphurated silver is mixed with mercury sublimate, and exposed to the fire, the mercury of the sublimate will unite with the sulphur, and carry it up in the form of cinnabar, whilst the marine acid of the sublimate unites with the silver into a luna cornea, which remains at the bottom of the glass. Fire alone is sufficient, if continued for some time, to expel the sulphur from silver.

1133
Purification.

From the baser metals, silver is purified by cupellation with lead. (See REFINING.) It always retains, however, after that operation, some small portion of copper, sufficient to give a blue colour to volatile spirits, which has been erroneously thought to proceed from the silver itself. It is purified from this admixture by melting it twice or thrice with nitre and borax. The scoria, on the first fusion, is commonly blue; on the second, green; and on the third, white, which is a mark of the purification being completed.

1134
Luna cornea reduced.

The most effectual means, however, of purifying silver, is by reviving it from luna cornea; because spirit of salt will not precipitate copper as it does silver. The silver may be recovered from luna cornea, by fusion with alkaline and inflammable fluxes; but, in these operations, some loss is always occasioned by the dissipation of part of the volatile calx, before the alkali or metal can absorb its acid.

1135
Mr Margraaff's method.

Mr Margraaff has discovered a method of recovering the silver with little or no loss; mercury assisted by volatile salts, imbibing it by trituration without heat. One part of luna cornea, and two of volatile salt, are to be ground together in a glass-mortar, with so much

VOL. IV. Part II.

water as will reduce them to the consistence of a thin paste, for a quarter of a hour, or more; five parts of pure quicksilver are then to be added, with a little more water, and the triture to be continued for some hours. A fine amalgam will thus be obtained; which is to be washed with fresh parcels of water, as long as any white powder separates. Nearly the whole of the silver is contained in the amalgam, and may be obtained perfectly pure by distilling off the mercury. The white powder holds a small proportion separable by gentle sublimation; the matter which sublimes is nearly similar to mercurius dulcis.

The colour of silver is debased by all the metals, and its malleability greatly injured by all but gold and copper. The English standard silver contains one part of copper to twelve and one-third of pure silver. This metal discovers in some circumstances a great attraction for lead; though it does not retain any of that metal in cupellation. If a mixture of silver and copper be melted with lead in certain proportions, and the compound afterwards exposed to a moderate fire, the lead and silver will melt out together, bringing very little of the copper with them; by this means silver is often separated from copper in large works. The effect does not wholly depend upon the different fusibility of the metals; for if tin, which is still more fusible than lead, be treated in the same manner with a mixture of silver and copper, the three ingredients are found to attract one another so strongly as to come all into fusion together. Again, if silver be melted with iron, and lead added to the mixture, the silver will forsake the iron to unite with the lead, and the iron will float by itself on the surface.

Silver is purified and whitened externally by boiling in a solution of tartar and common salt. This is no other than an extraction of the cupreous particles from the surface of the silver, by the acid of the tartar acted by the common salt.

M. Berthollet has lately discovered a method of imparting to the calx of silver a fulminating property, and that much more terrible than fulminating gold itself. His receipt for making it is, "Take cupelled silver, and dissolve it in the nitrous acid; precipitate the silver from the solution by lime-water, decant the clear liquor, and expose the precipitate three days to the open air. Mix this dried precipitate with the caustic volatile alkali, it will turn black; and when dried in the air, after decanting the clear liquor, is the fulminating powder required."

The properties of this powder are said to be so extraordinary, that it is impossible to imagine how any part of it can ever be separated from the rest after it is once prepared. To make this fulminate, it seems no sensible degree of heat is necessary, the contact of a cold body answering that purpose as well as any other. After it is once made, therefore, it must not be touched, but remain in the vessel in which it is dried; and so violent is the explosion, that it is dangerous to attempt it in larger quantities than a grain at a time.

For the same reason it undoubtedly follows, that no more than a grain ought to be made at a time, or at least in one vessel, because no part of it could ever afterwards be separated from the rest. We are told, that, "the wind having turned over a paper containing some atoms of this powder," (we ought to have

been informed how the atoms came there, considering what we have just now related,) "the portion touched by the hand fulminated, and of course that which fell upon the ground. A drop of water which fell upon this powder caused it to fulminate. A single grain of fulminating silver, which was in a glass cup, reduced the glass to powder, and pierced several doubles of paper.

1142
Fulmina-
ting cry-
stals.

"If the volatile alkali, which has been employed with the above powder, be put into a thin glass matras and boiled, then, on standing in the cold, small crystals will be found sublimed on the interior sides of the vessel, and covering the liquor. On touching one of these crystals the matras will be burst with considerable explosion.

1143
Cautions to
be used in
preparing
it.

"The dangerous properties of this powder suggest the necessity of not preparing it but when the face is covered with a mask with glass eyes; and to avoid the rupture of the glass cups, it is prudent to dry the fulminating silver in small metalline vessels." To this we may add, that as the powder does not fulminate when wet, it may in that state be put up in very small quantities on paper, to be fulminated afterwards as occasion offers. This will perhaps account for the appearance of the few atoms above mentioned on the paper which the wind overturned.

1144
Absurd
theory of
the anti-
phlogis-
tists.

With regard to the cause of this extraordinary fulmination we can say nothing satisfactory; the following curious reason is assigned by the antiphlogistons; which at once shows the futility of their theory, and sets in a very ridiculous light the hard words with which they would obscure the science of chemistry.

* Dephlo-
gisticated
air.
† Inflam-
mable air.

"The oxygenous principle* (say they) unites with the hydrogenous principle† of the volatile alkali, and form water in a vaporous state. This water (in a vaporous state) being instantaneously thrown into a state of vapour, possessing elasticity and expansive force, is the principal cause of this phenomenon, in which the

ries.

azotic‡ air which is disengaged from the volatile alkali, with its whole expansive power, has a great share." On this, as well as other theories, in which elastic fluids are alleged to be the cause of explosions, it is obvious to remark, that should we allow this to be the case, we are utterly at a loss to find a source of heat sufficient to rarefy the vapour to such a degree as is necessary for producing the effect ascribed to it. In the present case, we can scarce suppose a grain weight of metalline calx, already dry, to contain as much either of fire or water as is necessary to produce the effect; nor can we explain why the touch of any cold body, and which may be supposed to contain less fire than the calx itself, should produce such an effect. As to the oxygenous and hydrogenous principles, they were there before the touch, and ought to have produced their effects, not to mention that the water produced by them could not have amounted to the thousandth part of a grain. It is much more probable, therefore, that the whole is to be considered as an effect of electricity, though we cannot tell how the fluid comes here to be excited in such a violent manner.

bably ow-
ing to elec-
tricity.

§ 3. COPPER.

THIS is one of those metals which, from their destructibility by fire, and contracting rust in the air, are called *imperfect*. Of these, however, it is the most perfect and indestructible. It is of a reddish colour when pure; easily tarnishes in a moist air, and con-

tracts a green rust. It is the most sonorous of all the metals, and the hardest and most elastic of all but iron. In some of its states, copper is as difficultly extended under the hammer as iron, but always proves softer to the file; and is never found hard enough to strike a spark with flint or other stones; whence its use for chisels, hammers, hoops, &c. in the gunpowder works. When broke by often bending backwards and forwards, it appears internally of a dull red colour without any brightness, and of a fine granulated texture resembling some kinds of earthen ware. It is considerably ductile, though less so than either gold or silver; and may be drawn into wire as fine as hair, or beaten into leaves almost as thin as those of silver. The tenacity of its parts is very considerable; for a copper wire of $\frac{1}{16}$ of an inch diameter will support a weight of 299½ pounds without breaking. The specific gravity of this metal, according to Dr Lewis, is to that of water as 8.830 to 1.

Copper continues malleable when heated red; in which respect it agrees with iron; but is not, like iron, capable of being welded, or having two pieces joined into one. It requires for its fusion a stronger heat than either gold or silver, though less than that requisite to melt iron. When in fusion, it is remarkably impatient of moisture; the contact of a little water occasioning the melted copper to be thrown about with violence, to the great danger of the by-standers. It is, nevertheless, said to be granulated in the brass-works at Bristol, without explosion or danger, by letting it fall in little drops, into a large cistern of cold water covered with a brass-plate. In the middle of the plate is an aperture, in which is secured with Sturbridge clay a small vessel, whose capacity is not above a spoonful, perforated with a number of minute holes, through which the melted copper passes. A stream of cold water passes through the cistern. If suffered to grow hot, the copper falls liquid to the bottom, and runs into plates.

Copper, in fusion, appears of a bluish green colour, nearly like that of melted gold. Kept in fusion for a long time, it becomes gradually more and more brittle; but does not scorify considerably, nor lose much of its weight. It is much less destructible than any of the imperfect metals, being very difficultly subdued even by lead or bismuth. If kept in a heat below fusion, it contracts on the surface thin powdery scales; which, being rubbed off, are succeeded by others, till the whole quantity of the metal is thus changed into a scoria or calx, of a dark reddish colour. This calx does not melt in the strongest furnace fires; but, in the focus of a large burning mirror, runs easily into a deep red, and almost opaque, glass. A flaming fire, and strong draught of air over the surface of the metal, greatly promote its calcination. The flame being tinged of a green, bluish, or rainbow colour, is a mark that the copper burns.

This metal is very readily soluble by almost all saline substances; even common water, suffered to stand long in copper-vessels, extracts so much as to gain a coppery taste. It is observable, that water is much more impregnated with this taste, on being suffered to stand in the cold, than if boiled for a longer time in the vessel. The same thing happens in regard to the mild vegetable acids. The confectioners prepare the most acid syrups, even those of lemons and oranges, by

Copper. by boiling in clean copper-vessels, without the preparations receiving any ill taste from the metal; whereas, either the juices themselves, or the syrups made from them, if kept cold in copper vessels, soon become impregnated with a disagreeable taste, and with the pernicious qualities of the copper.

1151
Altered by
combina-
tion with
vegetable
acids.

By combination with vegetable acids, copper becomes in some respects remarkably altered. Verdigris, which is a combination of copper with a kind of acetous or tartareous acid, is partially soluble in distilled vinegar; the residuum, on being melted with borax and linseed oil, yields a brittle metallic substance, of a whitish colour, not unlike bell-metal. The copper also, when revived from the distilled verdigris, was found by Dr Lewis to be different from the metal before dissolution; but neither of these changes have yet been sufficiently examined.

1152
Amalga-
mation
with mer-
cury.

Copper, in its metallic state, is very difficultly amalgamated with mercury; but unites with it more easily if divided by certain admixtures. If mercury and verdigris be triturated together with common salt, vinegar, and water, the copper in the verdigris will be imbibed by the mercury, and form with it, as Boyle observes, a curious amalgam, at first so soft as to receive any impression, and which, on standing, becomes hard like brittle metals. Brass leaf likewise gives out its copper to mercury, the other ingredient of the brass separating in the form of powder.

1153
Dr Lewis's
method.

Easier methods of amalgamating copper are published by Dr Lewis in his notes on Wilson's Chemistry, p. 432. His receipts are,—“Dissolve some fine copper in aquafortis: when the menstruum will take up no more of the metal, pour it into an iron mortar, and add six times the weight of the copper, of mercury, and a little common salt: grind the whole well together with an iron pestle; and, in a little time, the copper will be imbibed by the mercury, and an amalgam formed, which may be rendered bright by washing it well with repeated affusions of water.

“*Another method.* Take the muddy substance which is procured in the polishing of copper plates with a pumice stone, and grind it well with a suitable portion of mercury, a little common salt, and some vinegar, in an iron mortar, (a marble one will do, if you make use of an iron pestle), till you perceive the mercury has taken up the copper.” The copper recovered from these amalgams retains its original colour, without any tendency to yellow. Even when brass is made use of for making the amalgam, the recovered metal is perfect red copper; the ingredient from which the brass received its yellowness being, as above observed, separated in the amalgamation.

1154
Brass, how
prepared.

Copper is the basis of several metals for mechanic uses; as brass, prince's metal, bell-metal, bath-metal, white copper, &c. Brass is prepared from copper and calamine, with the addition of powdered charcoal, cemented together, and at last brought into fusion. The calamine is to be previously prepared by cleansing it from adhering earth, stone, or other matters; by roasting, or calcining it; and by grinding it into a fine powder. The length of time, and degree of heat, requisite for the calcination of the calamine, are different according to the qualities of that mineral. The calamine, thus calcined, cleansed, and ground, is to be mixed with about a third or fourth part of char-

coal dust, or powdered pit-coal, as is done in some parts of England. The malleability of the basis is diminished by the use of pit-coal, which is therefore only employed for the preparation of the coarser kinds. To this composition of calamine and coal, some manufacturers add common salt, by which the process of making brass is said to be hastened. In Goslar, where the cadmia adhering to the insides of the furnaces is used instead of the native calamine, a small quantity of alum is added, by which they pretend the colour of the brass is heightened. With this composition, and with thin plates or grains of copper, the crucibles are to be nearly filled. The proportion of the calamine to the copper varies according to the richness of the former, but is generally as three to two. The copper must be dispersed through the composition of calamine and coal; and the whole must be covered with more coal, till the crucibles are full. The crucibles, thus filled, are to be placed in a furnace sunk in the ground, the form of which is that of the frustum of a hollow cone. At the bottom of the furnace, or greater basis of the frustum, is a circular grate, or iron-plate. This plate is covered with a coat of clay and horse-dung, to defend it from the action of the fire; and pierced with holes, through which the air maintaining the fire passes. The crucibles stand upon the circular plate, forming a circular row, with one in the middle. The fuel is placed betwixt the crucibles, and is thrown into the furnace at the upper part of it, or the lesser basis of the frustum. To this upper part or mouth of the furnace is fitted a cover made of bricks or clay, kept together with bars of iron, and pierced with holes. This cover serves as a register. When the heat is to be increased, the cover must be partly or entirely taken off, and a free draught is permitted to the external air, which passes along a vault under-ground to the ash-hole, through the holes in the circular grate or plate, betwixt the crucibles, and through the upper mouth, along with the smoke and flame, into an area where the workmen stand, which is covered with a large dome or chimney, through which the smoke and air ascend. When the heat is to be diminished, the mouth of the furnace is closed with the lid; through the holes of which the air, smoke, and flame pass. The crucibles are to be kept red-hot during eight or ten hours; and in some places much longer, even several days, according to the nature of the calamine. During this time, the zinc rises in vapour from the calamine, unites with the copper, and renders that metal considerably more fusible than it is by itself. To render the metal very fluid, that it may flow into one uniform mass at the bottom, the fire is to be increased a little before the crucibles are taken out, for pouring off the fluid metal into molds. From 60 pounds of good calamine, and 40 of copper, 60 pounds of brass may be obtained, notwithstanding a considerable quantity of the zinc is dissipated in the operation. The quantity of brass obtained has been considerably augmented since the introduction of the method now commonly practised, of granulating the copper; by which means a larger surface of this metal is exposed to the vapour of zinc, and consequently less of that vapour escapes. To make the finer and more malleable kinds of brass, besides the choice of pure calamine and pure copper,

Copper.

Copper. some manufacturers cement the brass a second time with calamine and charcoal; and sometimes add to it old brass, by which the new is said to be meliorated.

Brass is brittle when hot; but so ductile when cold, that it may be drawn into very fine wire, and beat into very thin leaves. Its beautiful colour, malleability, and its fusibility, by which it may be easily cast into moulds, together with its being less liable to rust than copper, render it fit for the fabrication of many utensils.

Although zinc be fixed to a certain degree in brass, by the adhesion which it contracts with the copper; yet when brass is melted, and exposed to a violent fire, during a certain time, the zinc dissipates in vapours, and even flames away, if the heat be strong enough; and if the fire is long enough continued, all the zinc will be evaporated and destroyed, so that what remains is copper.

2d 1154
Princesmetal.

Prince's metal is made by melting zinc in substance with copper; and all the yellow compound metals prepared in imitation of gold are no other than mixtures of copper with different proportions of that semimetal, taken either in its pure state, or in its natural ore calamine, with an addition sometimes of iron-filings, &c. Zinc itself unites most easily with the copper; but calamine makes the most ductile compound, and gives the most yellow colour. Dr Lewis observes, that a little of the calamine renders the copper pale; that when it has imbibed about $\frac{1}{2}$ its own weight, the colour inclines to yellow; that the yellowness increases more and more, till the proportion comes to almost one half; that on further augmenting the calamine, the compound becomes paler and paler, and at last white. The crucibles, in which the fusion is performed in large works, are commonly tinged by the matter of a deep blue colour.

1155
Bell-metal.

Bell-metal is a mixture of copper and tin; and tho' both these metals singly are malleable, the compound proves extremely brittle. Copper is dissolved by melted tin easily and intimately, far more so than by lead. A small portion of tin renders this metal dull-coloured, hard, and brittle. Bell-metal is composed of about ten parts of copper to one of tin, with the addition commonly of a little brass or zinc. A small proportion of copper, on the other hand, improves the colour and consistency of tin, without much injuring its ductility. Pewter is sometimes made from one part of copper and twenty or more of tin.

1156
Dr Lewis's observations on the specific gravity of the metal.

It has long been observed, that though tin is specifically much lighter than copper, yet the gravity of the compound, bell-metal, is greater than that of the copper itself. The same augmentation of gravity also takes place where the lighter metal is in the greatest proportion; a mixture even of one part of tin with two of copper, turning out specifically heavier than pure copper. Most metallic mixtures answer to the mean gravity of the ingredients, or such as would result from a bare apposition of parts. Of those tried by Dr Lewis, some exceeded the mean, but the greater number fell short of it; tin and copper were the only ones that formed a compound heavier than the heaviest of the metals separately.

1157
White copper.

White copper is prepared by mixing together equal parts of arsenic and nitre, injecting the mixture into a red-hot crucible, which is to be kept in a moderate

fire, till they subside, and flow like wax. One part of this mixture is injected upon four parts of melted copper, and the metal, as soon as they appear thoroughly united together, immediately poured out. The copper, thus whitened, is commonly melted with a considerable proportion of silver, by which its colour is both improved and rendered more permanent. The white copper of China and Japan appears to be no other than a mixture of copper and arsenic. Geoffroy relates, that, on repeated fusions, it exhaled arsenical fumes; and became red copper, losing, with its whiteness, one seventh of its weight.

§ 4. IRON.

IRON is a metal of a greyish colour; soon tarnishing in the air into a dusky blackish hue; and in a short time contracting a yellowish, or reddish rust. It is the hardest of all metals; the most elastic; and, excepting platina, the most difficult to be fused. Next to gold, iron has the greatest tenacity of parts; an iron wire, the diameter of which is the tenth part of an inch, being capable of sustaining 450 pounds. Next to tin, it is the lightest of all the metals, losing between a seventh and eighth part of its weight when immersed in water. When very pure, it may be drawn into wire as fine as horse-hair; but is much less capable of being beaten into thin leaves than the other metals, excepting only lead.

Iron grows red-hot much sooner than any other metal; and this, not only from the application of actual fire, but likewise from strong hammering, friction, or other mechanic violence. It nevertheless melts the most difficultly of all metals except manganese and platina; requiring, in its most fusible state, an intense, bright, white heat. When perfectly malleable, it is not fusible at all by the heat of furnaces, without the addition or the immediate contact of burning fuel; and, when melted, loses its malleability: all the common operations which communicate one of these qualities deprive it at the same time of the other; as if fusibility and malleability were in this metal incompatible. When exposed to the focus of a large burning mirror, however, it quickly fused, boiled, and emitted an ardent fume, the lower part of which was a true flame. At length it was changed into a blackish vitrified scoria.

From the great waste occasioned by exposing iron to a red but especially to a white heat, this metal appears to be a combustible substance. This combustion is maintained, like that of all other combustible substances, by contact of air. Dr Hook, having heated a bar of iron to that degree called *white heat*, he placed it upon an anvil, and blowed air upon it by means of bellows, by which it burnt brighter and hotter. Exposed to a white heat, it contracts a semivitreous coat, which bursts at times, and flies off in sparkles. No other metallic body exhibits any such appearance. On continuing the fire, it changes by degrees into a dark red calx, which does not melt in the most vehement heat procurable by furnaces, and, if brought into fusion by additions, yields an opaque black glass. When strongly heated, it appears covered on the surface with a soft vitreous matter like varnish. In this state, pieces of it cohere; and, on being

1159
Iron a combustible substance.

Iron. being hammered together, weld or unite, without discovering a juncture. As iron is the only metal which exhibits this appearance in the fire, so it is the only one capable of being welded. Those operations which prevent the superficial scorification, deprive it likewise of this valuable property: which may be restored again, by suffering the iron to resume its vitreous aspect; and, in some measure, by the interposition of foreign vitrescible matters; whilst none of the other metals will unite in the smallest degree, even with its own scoria.

1161
Contracts in fusion. Iron expands the least of all metals by heat. In the act of fusion, instead of continuing to expand, like the other metals, it shrinks; and thus becomes so much more dense, as to throw up such part as is unmelted to the surface; whilst pieces of gold, silver, copper, lead, or tin, put into the respective metals in fusion, sink freely to the bottom. In its return to a consistent state, instead of shrinking like the other metals, it expands; sensibly rising in the vessel, and assuming a convex surface, while the others become concave. This property, first observed by Reamur, excellently fits it for receiving impressions from moulds. By the increase of bulk which the metal receives in congelation, it is forced into the minutest cavities, so as to take the impression far more exactly than the other metals which shrink.

1162
Dissolved by all metals except lead and mercury. Iron is dissolved by all the metals made fluid, except lead; though none of them act so powerfully upon it as gold: but, as Cramer observes, if the iron contains any portion of sulphur, it can scarcely be made to unite at all with gold.

Among the semimetallic bodies, it is averse to an union with mercury; no method of amalgamating these two having yet been discovered; though quicksilver, in certain circumstances, seems in some small degree to act upon it. A plate of tough iron, kept immersed in mercury for some days, becomes brittle; and mercury will often adhere to and coat the ends of iron pestles used in triturating certain amalgams with saline liquors. Mr Jones has also discovered, that by plunging iron, while heated to an intense white heat, into mercury, the latter will adhere to the surface of the iron, and completely silver it over.

Next to mercury, zinc is the most difficultly combined with iron; not from any natural indisposition to unite, but from the zinc being difficultly made to sustain the heat requisite. The mixture is hard, somewhat malleable, of a white colour approaching to that of silver. Regulus of antimony, as soon as it melts, begins to act on iron, and dissolves a considerable quantity. If the regulus be stirred with an iron rod, it will melt off a part of it. Arsenic likewise easily mingles with iron, and has a strong attraction for it; forsaking all the other metals to unite with this. It renders the iron white, very hard, and brittle.

1163
Prussian blue. This metal is the basis of the fine blue pigment, called, from the place where it was first discovered, *Berlin* or *Prussian* blue. This colour was accidentally discovered about the beginning of the present century, by a chemist of Berlin, who, having successively thrown upon the ground several liquors from his laboratory, was much surprised to see it suddenly stained with a beautiful blue colour. Recollecting what liquors he had thrown out, and observing the same effects from a similar mixture, he prepared the blue for the use of

painters; who found that it might be substituted to ultramarine, and accordingly have used it ever since.

Several chemists immediately endeavoured to discover the composition of this pigment; and in the year 1724 Dr Woodward published the following process, in the Philosophical Transactions, for making it. "Alkalize together four ounces of nitre, and as much tartar as is directed for charcoal (n° 779). Mix this alkali well with four ounces of dried bullocks blood; and put the whole in a crucible covered with a lid, in which there is a small hole. Calcine with a moderate heat, till the blood be reduced to a perfect coal; that is, till it emits no more smoke or flame capable of blackening any white bodies that are exposed to it. Increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately, but sensibly, red.

"Throw into two pints of water the matter contained in the crucible, while yet red, and give it half an hour's boiling: decant this first water; and pour more upon the black charry coal, till it becomes almost insipid. Mix together all these waters; and reduce them, by boiling, to about two pints.

"Dissolve also two ounces of martial vitriol, and eight ounces of alum, in two pints of boiling water. Mix this solution when hot with the preceding lixivium also hot. A great effervescence will then be made: the liquors will be rendered turbid; and will become of a green colour, more or less blue; and a precipitate will be formed of the same colour. Filtrate, in order to separate this precipitate; upon which pour spirit of salt, and mix them well together; by which means the precipitate will become of a fine blue colour. It is necessary to add rather too much of the salt than too little, and till it no longer increases the beauty of the precipitate. The next day wash this blue, till the water comes off from it insipid; and then gently dry it."

1165
Mr Geoffroy's theory. Mr Geoffroy was the first who gave any plausible theory of this process, or any rational means of improving it. He observes, that the Prussian blue is no other than the iron of the vitriol revived by the inflammable matter of the alkaline lixivium, and perhaps a little brightened by the earth of alum; that the green colour proceeds from a part of the yellow ferruginous calx, or ochre, unrevived, mixing with the blue; and that the spirit of salt dissolves this ochre more readily than the blue part; though it will dissolve that also by long standing, or if used in too large quantity. From these principles, he was led to increase the quantity of inflammable matter; that there might be enough to revive the whole of the ferruginous ochre, and produce a blue colour at once, without the use of the acid spirit. In this he perfectly succeeded; and found, at the same time, that the colour might be rendered of any degree of deepness, or lightness, at pleasure. If the alkali is calcined with twice its weight of dried blood, and the lixivium obtained from it poured into a solution of one part of vitriol to six of alum, the liquor acquires a very pale blue colour, and deposits as pale a precipitate. On adding more and more of a fresh solution of vitriol, the colour becomes deeper and deeper, almost to blackness. He imagines with great probability, that the blue pigment, thus prepared, will prove more durable in the air, mingle more perfectly with other colours, and be less

Iron
1164
Dr Woodward's receipt for.

Iron.

less apt to injure the lustre of such as are mixed with or applied in its neighbourhood, than that made in the common manner; the tarnish to which common Prussian blue is subject, seeming to proceed from the acid, which cannot be separated by any ablution.

1166
Amusing
phenomenon in the
preparation.

He takes notice of an amusing phenomenon which happens upon mixture. When the liquors are well stirred together; and the circular motion, as soon as possible, stopped; some drops of solution of vitriol, (depurated by long settling), let fall on different parts of the surface, divide, spread, and form curious representations of flowers, trees, shrubs, flying insects, &c. in great regularity and perfection. These continue 10 or 12 minutes: and on stirring the liquor again, and dropping in some more of the solution of vitriol, are succeeded by a new picture.

1167
Mr Macquer's theory.

This theory is confirmed by Mr Macquer, in a Memoir printed in the year 1752. He observes, that the quantity of phlogiston communicated to the iron in this process is so great, as not only to cause the metal resist in a great measure the action of acids, and become totally unaffected by the magnet; but by a slight calcination it becomes entirely similar to other iron, and is at once deprived of its blue colour. He further observes, that fire is not the only means by which Prussian blue may be deprived of all the properties which distinguish it from ordinary iron. A very pure alkali produces the same effect. He has also discovered, that the alkali which has thus deprived the Prussian blue of all the properties which distinguish it from ordinary iron, becomes, by that operation, entirely similar to the phlogisticated alkali used for the preparation of Prussian blue.

1168
Phlogisticated alkali loses its alkaline properties.

By a more particular examination, he found, that the alkali might become perfectly saturated with the colouring matter; so that, when boiled on Prussian blue, it extracted none of its colour. When the salt was thus perfectly saturated, it seemed no longer to possess any alkaline qualities. If poured into a solution of iron in any acid, a single, homogeneous, and perfect precipitate, was formed; not green, as in Dr Woodward's process, but a perfect Prussian blue; which needed no acid to brighten its colour. A pure acid added to the alkali was not in the least neutralized, nor in the least precipitated the colouring matter. From hence Mr Macquer concludes, that, in the making of Prussian blue, vitriol is decomposed; because the iron has a strong attraction for the colouring matter, as well as the acid for the alkali; and the sum of the attraction of the acid to the alkali, joined to that of the iron for the colouring matter, is greater than the single attraction of the acid to the metal.

1169
Earths do not attract the colouring matter

Another very important phenomenon is, that earths have not the same attraction for this colouring matter that metallic substances have. Hence, if an alkali saturated with this colouring matter be poured into a solution of alum, no decomposition is effected, nor any precipitate formed. The alum continues alum, and the alkali remains unchanged. From this experiment Mr Macquer concludes that alum does not directly contribute to the formation of the Prussian blue. The purpose he thinks it answers is as follows. Fixed alkaline salts can never be perfectly saturated with phlogistic matter by calcination; alkalies, therefore, though calcined with inflammable substances, so as to make a

proper lixivium for Prussian blue, remain still alkaline. Hence, when mixed with a solution of green vitriol, they form, by their purely alkaline part, a yellow precipitate, so much more copious, as the alkali is less saturated with phlogiston. But nothing is more capable of spoiling the fine colour of the Prussian blue, than an admixture of this yellow precipitate: it is therefore necessary to add a quantity of alum, which will take up the greatest part of the purely alkaline salt; and of consequence the quantity of yellow ferruginous precipitate is much diminished. But the earth of alum, being of a fine shining white, does not in the least alter the purity of the blue colour, but is rather necessary to dilute it. From all this it follows, that it is a matter of indifference whether the green precipitate is to be again dissolved by an acid, or the alkaline part of the lixivium saturated with alum or with an acid, before the precipitate is formed. The latter indeed seems to be the most eligible method.

Most alkalies obtained from the ashes of vegetables, being combined, by their combustion, with a portion of inflammable matter, are capable of furnishing a quantity of Prussian blue, proportionable to the quantity of colouring matter they contain, even without the necessity of mixing them with a solution of iron; because they always contain a little of this metal dissolved, some of which may be found in almost all vegetables; therefore it is sufficient to saturate them with an acid. Henckel observed the production of this blue in the saturation of the fossil alkali, and recommended to chemists to inquire into its nature.

The theories of Geoffroy, Macquer, &c. however, with respect to Prussian blue, have now given place to that of Mr Scheele; who has examined the substance with the utmost care, and found the colouring matter to consist of an extremely volatile substance, capable of uniting with and neutralizing alkalies, but easily expelled from them by any other acid, even by that of fixed air. He begins his dissertation on this subject by observing, that the solution of alkali calcined with dried blood, which he calls *lixivium sanguinis*, by exposure to the air, loses its property of precipitating the iron of a blue colour; and that the precipitate thus obtained is entirely soluble in the acid. In order to determine whether the air had thus undergone any change, he put some newly prepared lixivium into a glass vessel well sealed with rosin; but after some time finding no change on the lixivium or on the air contained in the vessel, he began to think that this might be occasioned by the absence of fixed air, which always abounds in the open atmosphere, though not in any confined portion of it, at least in an equal proportion. Having therefore filled a glass vessel with fixed air, he poured into it a little lixivium sanguinis; and next day found, that it threw down from green vitriol a precipitate entirely soluble in acids. With other acids he obtained no precipitate.

On inverting the experiment, and mixing some green vitriol with lixivium sanguinis, the mixture grew yellow; and he found this addition capable of fixing the colouring matter so, that neither the acid of fixed air nor any other could expel it from the alkali. For having poured the mixture above mentioned into a solution of green vitriol, and afterwards supersaturated the

The matter fixed by the addition of some green vitriol to the lixivium.

Iron. the lixivium with acid, he obtained a considerable quantity of blue. To the same lixivium sanguinis, in which a small quantity of green vitriol was dissolved, he afterwards added of the other acids somewhat more than was necessary for its saturation; and though this was done, a considerable quantity of Prussian blue was afterwards obtained. Again, having precipitated a solution of green vitriol with alkali, and boiled the precipitate for some minutes in lixivium sanguinis, part of it was dissolved: the filtered lixivium underwent no change when exposed to the open air or to the aerial acid, and precipitated the solution of vitriol of a blue; and though the lixivium was supersaturated with acid, and some green vitriol added, a very beautiful Prussian blue was obtained. This, however, will not hold when a perfectly dephlogisticated calx of iron is employed, of which none can be dissolved by the lixivium sanguinis; nor will any Prussian blue be obtained by precipitating with lixivium sanguinis a perfectly dephlogisticated solution of iron in nitrous acid.

1175 Calx of iron soluble in lixivium sanguinis;
1176 But not when highly dephlogisticated.
1177 The colouring matter taken up by the air after it has been expelled by acids.
To determine what had become of the colouring matter in those experiments where it seemed to have been dissipated, some lixivium sanguinis was poured into a vessel filled with aerial acid. It was kept well corked during the night, and next day a piece of paper dipped in a solution of green vitriol was fixed to the cork, pencilling it over with two drops of a solution of alkali in water. The paper was thus soon covered with precipitated iron; and on being taken out two hours afterwards, and dipped in muriatic acid, became covered with most beautiful Prussian blue. The same thing happened when lixivium sanguinis supersaturated with vitriolic acid was employed; for in this case also the air was filled with the colouring matter, capable of being in like manner absorbed by the calx of iron. But though from these experiments it is plain that acids expel this colouring substance from the lixivium, a given quantity of air is only capable of receiving a certain quantity of it; for the same mixture removed into another vessel imparts the colouring property to the air it contains according to its quantity. On putting perfectly dephlogisticated calx of iron upon the papers, no Prussian blue was formed; but the muriatic acid dissolved the calx entirely.

1178 The colouring matter expelled by distillation with vitriolic acid.
Our author having now assured himself that acids really attract the alkali more than the colouring matter, proceeded to try the effects of distillation. Having therefore supersaturated some lixivium sanguinis with vitriolic acid, he distilled the mixture in a glass retort with a gentle fire. When about one-third had passed over, he changed the receiver, and continued the operation till one-half was distilled. The first product had a peculiar taste and smell; the air in the receiver was filled with colouring matter, and the aqueous fluid was also strongly impregnated with it, as appeared by its forming a fine Prussian blue with phlogisticated calx of iron. Part of it being exposed to the open air for some hours, entirely lost its power, and the product of the second operation was no other than water mixed with a little vitriolic acid.

1179 Attempts to procure the colouring matter by itself.
The next step was to procure, if possible, the colouring matter by itself; and this he attempted to obtain from the Prussian blue, rather than the lixivium sanguinis, as he would thus not only avoid the troublesome calcination of the alkali and blood, but

obtain the colouring matter in much larger quantity than could be done from the lixivium. On examining several kinds of this pigment, he found in them evident marks of sulphur, volatile alkali, vitriolic acid, and volatile sulphureous acid; all of which substances are to be found in the lixivium sanguinis, as well as in that of foot, and adhere to the precipitate in the preparation of Prussian blue. Finding, however, that he could not obtain his purpose by any kind of analysis of these by fire alone, he had recourse to a neutral salt used by chemists for discovering iron in mineral waters. This is formed by digesting caustic fixed alkali on Prussian blue, which effectually extracts the colour from it even in the cold, in a very short time, and being neutralized, may easily be reduced into a dry form. But it is not entirely to be depended upon for this purpose; for it always contains some iron, which indeed is the medium of its connection with the alkali. The lixivium sanguinis is preferable, though even this contains some iron, as well as the lixivium of foot; our author's experiments, however, were made with the neutral salt, for the reasons already mentioned.

1180 Neutral salt for discovering iron in mineral waters.
1181 Effects of distilling this salt with oil of vitriol.
1. An ounce of the salt was dissolved in a glass retort in four ounces of water, afterwards adding three drachms of concentrated vitriolic acid; and the mixture was distilled with a gentle fire. The mass grew thick as soon as it began to boil; from a great quantity of Prussian blue, a quantity of the colouring matter appeared by the smell to penetrate the lute; and part of it was absorbed by the air in the receiver, as in former experiments. The distillation was continued till about an ounce had passed into the receiver. The blue mass remaining in the retort was put into a strainer, and a piece of green vitriol put into the liquid which passed through; but by this last no Prussian blue was produced. The blue which remained in the filter was again treated with lixivium tartari; the solution freed from its ochre by filtration, and the clear liquor committed a second time to distillation with vitriolic acid. Prussian blue was again separated, though in smaller quantity than before, and the colouring matter came over into the receiver. After one third of the matter had passed over, that which had been obtained by the first distillation was added to it, the Prussian blue was separated from the lixivium in the retort, and extracted a third time. Some Prussian blue was formed again, though in much smaller quantity; whence it is apparent that Prussian blue may at last be totally decomposed by means of alkali. Lime, or terra ponderosa, likewise extract the blue colour, and show the same phenomena as alkali.

1182 Colouring matter united with volatile alkali.
With volatile alkali a compound, consisting of the alkali, iron, and colouring matter, is formed, which shows the same phenomena with that formed with fixed alkali. By distillation *per se* after it has been dissolved in water, the liquor grows thick in consequence of a separation of Prussian blue, and volatile alkali passes over into the receiver. This volatile spirit is impregnated with the colouring matter: it is not precipitated by lime-water; but green vitriol is precipitated by it; and on adding an acid, Prussian blue is formed. If a piece of paper, dipped in a solution of green vitriol, be exposed to the vapour of this alkali, it is soon decomposed; and if the same be pencilled over with muriatic acid, it instantly becomes blue.

blue. On exposing the liquor to the open air, it all evaporates, leaving pure water behind.

As in all the operations with vitriolic acid hitherto related, some small quantity of it passes into the receiver, our author shows how to deprive the colouring matter of that vitriolic taint. For this purpose nothing more is necessary than to put a little chalk into the matter, and redistil it with a very gentle heat; the acid unites with the chalk, and the colouring matter goes over in its greatest purity. In order to hinder, as much as possible, the escape of the volatile colouring matter through the lute, he makes use of a small receiver, putting into it a little distilled water, and placing it so that the greater part shall be immersed in cold water during the operation. The water impregnated with this colouring matter has a peculiar but not disagreeable smell, a taste somewhat approaching to sweet, and warm in the mouth, at the same time exciting cough. When rectified as above directed, it appears to be neither acid nor alkaline; for it

neither reddens paper dyed with lacmus, nor does it restore the colour of such paper after it has been made red; but it renders turbid the solutions of soap and hepar sulphuris. The same liquor mixed with fixed alkali, though it contains a superabundance of colouring matter, restores the blue colour of paper reddened by an acid. By distillation to dryness, there goes over a part of the colouring matter which disengages itself from the alkali; the residuum is soluble in water, and has all the properties of the best lixivium sanguinis; but, like the true lixivium, it is decomposed by all the acids, even by that of fixed air. With caustic volatile alkali it forms a kind of ammoniacal salt; which, however, always smells volatile, though the colouring matter be in ever so great proportion. By distillation the whole instantly rises, and nothing but pure water is left in the retort.

Magnesia precipitated from Epsom salt by caustic volatile alkali, was dissolved in the colouring matter by allowing them to stand together for several days in a warm close bottle. On exposure to the open air, the magnesia separated from it by its superior attraction for aerial acid, and formed on the surface of the water a pellicle like that of cream of tartar. This solution was likewise decomposed by alkalies and lime-water.

The colouring matter dissolves but a very small quantity of terra ponderosa, which may be afterwards precipitated by vitriolic and even by aerial acid.

Pure clay, or the basis of alum, is not attacked by it. Lime is dissolved in a certain quantity. The superabundant portion should be separated by filtration; and as the liquor contains, besides the combined lime, the portion which water itself is able to take up, in order to free it from this, precisely the same quantity of water impregnated with aerial acid is to be added as is requisite for precipitating an equal quantity of lime-water. The colouring matter, thus saturated with lime, is to be filtered again, and then to be preserved in a well closed bottle to prevent the access of fixed air. This solution is decomposed by all the acids, and by the pure or caustic alkalies. By distillation the colouring matter rises, and nothing but pure lime is left in the retort.—This solution of lime ap-

pears to our author to be so perfectly saturated, that he employed it in preference to any other in the experiments he made on metals, and which we are now about to relate.

From the trials made by Mr Scheele, it appears that the colouring matter has no effect upon any metal or metallic solution, excepting those of silver and quicksilver in nitrous acid, and that of iron in fixed air. The first is precipitated in a white powder; the second in a black one; and the third assumes a sea-green colour, which afterwards turns to blue. With metallic calces it produces the following phenomena. 1. Gold precipitated by aerated alkali becomes white. 2. The fixed air is disengaged from a precipitate of silver with a slight effervescence. 3. Calx of mercury is dissolved, and yields crystals by gentle evaporation. 4. The calx of copper precipitated by aerated alkali effervesces, and assumes a faint citron colour. 5. Calx of iron precipitated from its solution in the vitriolic acid by the same alkali, effervesces, and assumes a dark blue colour. 6. Precipitated cobalt shows some signs of effervescence, and changes into a yellowish brown colour. The other calces are not acted upon.

The precipitating liquor above mentioned, poured into metallic solutions, produces the following appearances by means of double elective attraction. 1. Gold is precipitated of a white colour, but by adding a superabundant quantity of the precipitating liquor the calx is redissolved. The second solution is colourless as water. 2. Silver is precipitated in form of a white substance of the consistence of cheese; by adding more of the liquor the precipitate is redissolved, and the solution is not decomposed either by sal-ammoniac or marine acid. 3. Corrosive sublimate apparently undergoes no change, though it is in reality decomposed; the calx being dissolved in the colouring matter. Mercury dissolved in the nitrous acid without heat, is precipitated in form of a black powder. 4. The solutions of tin and bismuth are precipitated, but the calx is not acted upon by the colouring matter. 5. The same effects are produced on the solution of butter of antimony, as well as on that of well dephlogisticated calx of iron. 6. Blue vitriol is precipitated of a yellow citron colour: if more of the precipitating liquor be added, the precipitate is redissolved into a colourless liquor; and a colourless solution of the same calx is likewise obtained by volatile alkali. On adding more of the solution of blue vitriol, the solution likewise disappears, and the liquor assumes a green colour. Acids dissolve a portion of this precipitate, and the remainder is white. The muriatic acid dissolves the precipitate completely, but lets it fall again on the addition of water. 7. The solution of white vitriol yields a white precipitate, which is not redissolved by addition of the precipitating liquor, but is soluble in acids. These solutions smell like the colouring matter, which may be separated from them by distillation. 8. Green vitriol is precipitated, first of a yellowish brown colour, which soon changes to green, and then becomes blue on the surface. Some hours afterwards the precipitate subsides to the bottom of the vessels, and then the whole mixture turns blue; but on adding any acid the precipitate becomes instantly blue. If a very small quantity of green vitriol be put into the precipitating liquor, the

Prussian blue yields volatile alkali by distillation.

1198
Appearances on distilling other precipitates thrown down by Prussian alkali.

Lastly, our author undertook an investigation of the constituent parts of the colouring matter itself; and in this he succeeded in such a manner as must do honour to his memory, at the same time that it promises to be a real and lasting improvement to science, by showing a method of preparing this valuable pigment without that nauseous and horrid ingredient, blood, which is now used in great quantities for that purpose.—His first hint concerning this matter seems to have been taken from an observation of the air in his receiver accidentally taking fire from the neighbourhood of a candle. It burned without any explosion, and he was able to inflame it several times successively. Wishing to know whether any fixed air was contained in the colouring matter, he filled a retort half full of the liquor containing the colouring matter, and applying a receiver immediately after, gave the retort a brisk heat. As soon as the receiver was filled with thick vapours of the colouring matter, he disjoined it, and, inflaming the vapour by a little burning sulphur introduced into the cavity, found that the air which remained threw down a precipitate from lime-water.

“Hence (says he) it may be concluded, that the aerial acid (A) and phlogiston exist in this colouring matter.”

It has been asserted by several chemists, that Prussian blue by distillation always yields volatile alkali.—To determine this, Mr Scheele prepared some exceedingly pure from the precipitating liquor above mentioned and green vitriol; distilling it afterwards in a glass retort, to which he adapted a receiver containing a little distilled water. The operation was continued till the retort became red-hot. In the receiver was found the colouring matter and volatile alkali, but no oil; the air in the receiver was impregnated with aerial acid, and the same colouring matter; the residuum was very black, and obeyed the magnet. On substituting, instead of the Prussian blue, the precipitates of other metallic substances precipitated by the Prussian alkali, the results were: 1. The yellowish brown precipitate of cobalt yielded the very same products with Prussian blue itself; the residuum in the retort was black. 2. The yellow precipitate of copper took fire, and emitted, from time to time, sparks during the distillation. It produced little colouring matter, but a greater quantity of aerial acid and volatile alkali than had been obtained by the former precipitates. A sublimate arose in the neck of the retort, but in too small a quantity to make any experiment; the residuum was reduced copper. 3. The precipitate of zinc yielded the same with Prussian blue. 4. That of silver yielded likewise volatile alkali and fixed air, but chiefly colouring matter; a sublimate containing some silver arose into the neck of the retort; the residuum was reduced

VOL. IV. PART II.

silver. 5. Calx of mercury crystallized by means of the colouring matter, yielded some of that matter, but scarce any mark of volatile alkali. Some mercury, with a portion of the original compound, arose in the neck of the retort.

From these experiments Mr Scheele concluded, that the colouring matter of Prussian blue was composed of volatile alkali and an oily matter. He was confirmed in this conjecture, by obtaining Prussian blue from green vitriol and spirit of hartshorn recently distilled on the addition of muriatic acid. The same product was obtained by means of the volatile spirit drawn from ox's blood; so that nothing now remained, but to imitate these natural processes by artificially combining the two ingredients together. For this purpose he distilled a mixture of volatile salt and unctuous oil; a mixture of the same alkali with animal fat, and with oil of turpentine; a mixture of quick-lime, sal-ammoniac, and auxunge, with others of a similar kind; but in vain. He began therefore to conclude, that as long as the volatile alkali contained any water, it could not enter into an union sufficiently intimate with the other principles to form the colouring matter; and finding also that the coal of blood, mixed with salt of tartar, yielded very good lixivium sanguinis, he concluded that no oily matter was necessary for the success of the experiment.

Thus was our author led to make the following decisive trials, which at once accomplished his purpose, and showed the truth of the principles he had assumed. Three table-spoonfuls of charcoal powder were mixed with an equal quantity of alkali of tartar, and the mixture put into a crucible. A similar mixture was put into another crucible, and both put into a fire, and kept red-hot for about a quarter of an hour. One of them was then taken out, and the contents thrown, while perfectly red-hot, into eight ounces of water. At the same time he put into the other quantity an ounce of sal-ammoniac in small pieces, agitating the whole briskly together, and taking care at the same time to push the sal-ammoniac down towards the bottom of the crucible, which he replaced in the fire. Observing in two minutes after, that no ammoniacal vapours arose, the whole mass was thrown, when red-hot, into eight ounces of water. The former lixivium, into which no sal-ammoniac had been put, yielded no Prussian blue; but the latter showed the same phenomena with the best lixivium sanguinis, and produced a great quantity of blue. By mixing plumbago with the alkali instead of charcoal, a tolerable lixivium was obtained.

“From these experiments (says Mr Scheele), it appears, that the volatile alkali is capable of uniting with the carbonaceous matter, after it has been sublimized by a strong heat; that it thus acquires the remarkable property of combining so firmly with salt of tartar as to be able to sustain the most violent degree of heat; and when this lixivium is dissolved in water, there is obtained lixivium sanguinis, as it is called.—It is now easy to explain what happens in the distillation heat.

1199
Ingredients contained in the colouring matter.

1200
Unsuccessful attempts to prepare it artificially.

1201
True method of forming it.

1202
Volatile alkali capable of uniting with phlogiston and fixed alkali, so as to sustain a great degree of heat.

(A) This reasoning seems not to be sufficiently conclusive; for late experiments have shown that inflammation is generally attended with the production of fixed air, which could not be proved to have an existence either in the materials or common atmosphere before.

Has very little tenacity.

lation of Prussian blue, as well as in that of the other above mentioned metallic precipitates.—In the distillation of Prussian blue, for instance, the calx of iron attracts a portion of phlogiston from the colouring matter. The aerial acid being thus disengaged, must go over into the receiver with the volatile alkali, which is set free at the same instant; but as the calx of iron in the heat of this distillation cannot unite with more phlogiston, a portion of the colouring matter, not decomposed, must likewise arise. If the calx of iron could combine with the whole of the phlogiston, there would come nothing over into the receiver but aerial acid and volatile alkali. In order to prove this, I distilled a mixture of six parts of manganese finely powdered, and one part of pulverized Prussian blue, and obtained nothing but aerated volatile alkali, without the least mark of colouring matter."

Mr Scheele further remarks, that this colouring matter may probably be obtained in an aerial form, though he had not been able to do so. It is also worth notice, that, excepting the solutions of silver and mercury in nitrous acid, the colouring matter of Prussian blue is not able to decompose any other by a single elective attraction. Now, as we know that Prussian blue is not soluble in acids, it naturally follows, that the colouring matter has a greater affinity with iron than acids have, notwithstanding there is no precipitation perceived when this matter is mixed with the solution of vitriol of iron. "It may not be easy (says Mr Scheele) to give a satisfactory explanation of this phenomenon."

Iron deflagrates with nitre, and renders the salt alkaline and caustic. A part of the iron is thus rendered soluble, along with the alkaliized salt. A mixture of equal parts of iron filings and nitre, injected into a strongly heated crucible, and, after the detonation, thrown into water, tinges the liquor of a violet or purplish blue colour. This solution, however, is not permanent. Though the liquor at first passes through a filter, without any separation of the iron; yet, on standing for a few hours, the metal falls to the bottom, in form of a brick-coloured powder. Volatile alkalies instantly precipitate the iron from this fixed alkaline solution.

Iron readily unites with sulphur; and when combined with it, proves much easier of fusion than by itself. A mixture of iron filings and sulphur, moistened with water, and pressed down close, in a few hours swells and grows hot; and, if the quantity is large, bursts into flame.

By cementation with inflammable matters, iron imbibes a larger quantity of phlogiston; and becomes much harder, less malleable, and more fusible. It is then called *steel*. See METALLURGY, and STEEL.

§ 5. LEAD.

LEAD is a pale or livid-white metal, soon losing its brightness in the air, and contracting a blackish or greyish ash-colour. It is the softest and most flexible of all metallic bodies; but not ductile to any great degree, either in the form of wire or leaf; coming far short, in this respect, of all other metals. It has also the least tenacity of all metallic bodies; a leaden wire

of $\frac{1}{16}$ of an inch diameter being capable of supporting only $29\frac{1}{4}$ pounds. Lead has, however, a considerable specific gravity; losing, when immersed in water, between $\frac{1}{11}$ and $\frac{1}{12}$ of its weight. It is of all metals the most fusible, excepting only tin and bismuth. The plumbers cast thin sheets of lead upon a table or mould, covered with a woollen, and above this with a linen, cloth, without burning or scorching the cloths. The melted lead is received in a wooden case without a bottom; which being drawn down the sloping table by a man on each side, leaves a sheet of its own width, and more or less thin according to the greater or less celerity of its descent. For thick plates, the table is covered over with moistened sand, and the liquid metal conducted evenly over it, by a wooden strike, which bears on a ledge at each side.

Some have preferred, for mechanic uses, the milled lead, or flatted sheets, to the cast; as being more equal, smooth, and solid. But whatever advantage of this kind the milled sort may appear to have at first, they are not found to be very durable. When the lead is stretched between the rollers, its cavities must necessarily be enlarged. The particles of metal that may be squeezed into them can have no union or adhesion with the contiguous particles; and, of consequence, must be liable, from bending, blows, jars, &c. to start out again, and leave the mass spongy and porous.

Lead yields the dullest and weakest sound of all metallic bodies. Reaumur observes, that it is rendered sonorous by casting a small quantity into a spherical or elliptical segment, as in the bottom of an iron-ladle; from hence he conjectures, that the sound of the sonorous metals might be improved for the bells of clocks, &c. by giving them a similar form.

Though this metal very soon loses its lustre, and tarnishes in the air, it resists much longer than iron or copper the combined action of air and water, before it is decomposed or destroyed; and hence it is exceedingly useful for many purposes to which these metals can by no means be applied. When just become fluid, lead looks bright like quicksilver; but immediately contracts a variously coloured pellicle on the surface. If this is taken off, and the fire continued, a fresh pellicle will always be formed, till the metal is by degrees changed into a dusky powder or calx. The injection of a little fat, charcoal-powder, or other inflammable matter, prevents this change, and readily revives the calx into lead again. It is said, that lead, recovered from its calces, proves somewhat harder and whiter than at first, as well as less subject to tarnish in the air.

The blackish calx or ashes of lead become of a very different appearance if the calcination is continued with a fire so moderate as not to melt them, and particularly if exposed to flame. By this treatment it is said that they become first yellow; then they are called *massicot* or *yellow lead*. This colour becomes gradually more and more intense, till at last the calx is of a deep red; and then is called *minium* or *red lead*; but it is certain, that by proper management this calx never becomes yellow, assuming a reddish colour from the beginning. Too great a heat makes it irrecoverably yellow. It can be more easily prepared without exposure

Rendered
sonorous.1212
Calcined.1213
Minium.

Lead. exposure to the flame. The degree of heat necessary for converting it into minium is between 600 and 700 of Fahrenheit.

1214
Litharge.

If, instead of keeping this calx in a continued moderate heat, it be suddenly fused, the matter then puts on a foliated appearance, changing to a dull kind of brick-colour when powdered, and is then called *litharge*. Most of this substance is produced by refining silver with lead (see REFINING); and is of two kinds, white and red. These two are distinguished by the names of *litharge of gold*, and *litharge of silver*. The most perfect is that called *litharge of gold*: the pale sort contains a considerable proportion of lead in its metallic state; and even the highest coloured litharge is seldom free from a little metallic lead, discoverable and separable by melting the mass in a crucible; when the lead subsides to the bottom.

1215
Phenomena with other metals.

Lead mingles in fusion with all the metals except iron, with which it refuses any degree of union as long as the lead preserves its metallic form. On continuing the fire, the lead, scorifying or calcining, absorbs the phlogistic principle of the iron, and consequently promotes the calcination of that metal; both being at length reduced to calces. The fusible calx of lead easily unites with the calx of iron, and both melt together into an opaque brown or blackish glass. Copper does not unite with melted lead till the fire is raised so high as to make the lead smoke and boil, and of a bright red heat. Pieces of copper, now thrown in, soon dissolve and disappear in the lead: the mixture, when cold, is brittle, and of a granulated texture. The union of these two metals is remarkably slight. If a mixture of copper and lead is exposed to a fire no greater than that in which lead melts, the lead almost entirely runs off by itself; a separation of which no other example is known. What little lead is retained in the pores of the copper, may be scorified, and melted out, by a fire considerably less than is sufficient to fuse copper. If any of the copper is carried off by the lead, it swims unmelted on the surface.

Gold and silver are both dissolved by lead in a slight red heat. They are both rendered extremely brittle by the minutest quantity of this metal; though lead is rendered more ductile by a small quantity of either of them. In cupellation, a portion of lead is retained by gold, but silver parts with it all. On the other hand, in its eliquation from copper, if the copper contains any of the precious metals, the silver will totally melt out with the lead, but the gold will not. The attraction of lead to copper, however slight, is greater than that of copper to iron: a mixture of copper and iron being boiled in melted lead, the copper is imbibed by the lead, and the iron thrown up to the top. Silver is in like manner imbibed from iron by lead; whilst tin, on the contrary, is imbibed from lead by iron. If two mixtures, one of lead and tin, and another of iron and silver, be melted together, the result will be two new combinations, one of the tin with the iron at the top, the other with the lead and silver at the bottom: how carefully soever the matter be stirred and mixed in fusion, the two compounds, when grown cold, are found distinct, so as to be parted with a blow.

This metal is soluble in alkaline lixivium and expres-

sed oils. Plates of lead boiled in alkaline lixivium, have a small part dissolved, and a considerable quantity corroded: the solution stains hair black. Lead, fused with fixed alkaline salts, is in part corroded into a dark-coloured scoria, which partially dissolves in water. Expressed oils dissolve the calces of lead, by boiling, in such large quantities as to become thick and consistent: hence plasters, cements for water-works, paint for preserving nets, &c. Acids have a greater affinity with leads than oils have. If the common plaster, composed of oil and litharge, be boiled in distilled vinegar, the litharge will be dissolved, and the oil thrown up to the top. The oil thus recovered, proves soluble like essential oils in spirit of wine; a phenomenon first taken notice of by Mr Geoffroy.

§ 6. TIN.

THE colour of this metal resembles silver, but is somewhat darker. It is softer, less elastic, and sonorous, than any other metal except lead. When bent backwards and forwards, it occasions a crackling sound, as if torn asunder. It is the lightest of all the malleable metals, being little more than seven times specifically heavier than water. The tenacity of its parts also is not very considerable; a tin wire of $\frac{1}{8}$ of an inch diameter being able to support only 49½ pounds.

Tin is commonly reckoned the least ductile of all metals except lead; and certainly is so, in regard to ductility into wire, but not in regard to extensibility into leaves. These two properties seem not to be so much connected with one another as is generally imagined. Iron and steel may be drawn into very fine wire, but cannot be beat into leaves. Tin, on the other hand, may be beat into very thin leaves, but cannot be drawn into wire: gold and silver possess both properties in a very eminent degree; whilst lead, notwithstanding its flexibility and softness, cannot be drawn into fine wire, or beat into thin leaves. It melts the most easily of all the metals; about the 430th degree of Fahrenheit's thermometer. Heated till almost ready to melt, it becomes so brittle that large blocks may be easily beat to pieces by a blow. The purer sort, from its facility of breaking into long shining pieces, is called *grain-tin*. Melted, and nimbly agitated at the instant of its beginning to congeal, it is reduced into small grains or powder.

With the heat necessary for fusion, it may also be calcined; or at least so far deprived of its phlogiston as to appear in the form of a grey calx, which may be entirely reduced to tin by the addition of inflammable matter. The calcination of tin, like that of lead, begins by the melted metal losing its brightness, and contracting a pellicle on its surface. If the fire is raised to a cherry-red, the pellicle swells and bursts, discharging a small bright flame of an arsenical smell. By longer continuance in the fire, the metal is converted first into a greyish, and then into a perfectly white calx, called *patty*, which is used for polishing glass and other hard bodies.

The calx of tin is the most refractory of all others. Even in the focus of a large burning mirror, it only softens a little, and forms crystalline filaments. With

glass

Tin.

glass of bismuth, and the simple and arsenicated glasses of lead, it forms opaque milky compounds. By this property it is fitted for making the basis of the imperfect glasses called *enamels*; (see GLASS and ENAMEL). The author of the Chemical Dictionary relates, "that having exposed very pure tin, singly, to a fire as strong as that of a glass-house furnace, during two hours, under a muffle, in an uncovered test, and having then examined it, the metal was found covered with an exceedingly white calx, which appeared to have formed a vegetation; under this matter was a reddish calx, and an hyacinthine glass; and lastly, at the bottom was a piece of tin unaltered. The experiment was several times repeated with the same success."

1219
Affinity of
tin with
arsenic.

Nitre deflagrates with tin, and hastens the calcination of this as well as of other imperfect metals. The vapours which rise from tin, by whatever method it is calcined, have generally an arsenical smell. Tin melted with arsenic falls in great part into a whitish calx: the part which remains uncalcined proves very brittle, appears of a white colour, and a sparkling plated texture, greatly resembling zinc. The arsenic is strongly retained by the tin, so as scarcely to be separable by any degree of fire; the tin always discovering, by its augmentation in weight, that it holds a portion of arsenic, though a very intense fire has been used. Hence, as the tin ores abound in arsenic, the common tin is found also to participate of that mineral.

1220
Arsenic se-
parable
from tin.

Henckel discovered a method of separating actual arsenic from tin; namely, by slowly dissolving the tin in eight times its quantity of an aqua regia made with sal ammoniac, and setting the solution to evaporate in a gentle warmth: the arsenic begins to concrete whilst the liquor continues hot, and more plentifully on its growing cold, into white crystals. M. Margraaf, in the Berlin Memoirs for 1747, has given a more particular account of this process. He observes, that the white sediment which at first separates during the dissolution, is chiefly arsenical; that Malacca tin, which is accounted one of the purest sorts, yielded no less than $\frac{1}{4}$ th its weight of arsenical crystals; that some sorts yielded more; but that tin extracted from a particular kind of ore, which contained no arsenic, afforded none. That the crystals were truly arsenical, appeared from their being totally volatile; from their subliming (a little fixed alkaline salt being added to absorb the acid) into a colourless pellucid concrete; from the sublimate, laid on a heated copper-plate, exhaling in fumes of a garlic smell; from its staining the copper white; and from its forming, with sulphur, a compound similar to the yellow or sulphurated arsenic. He found that the arsenic was separable also by means of mercury; an amalgam of tin being long triturated with water, and the powder which was washed off committed to distillation, a little mercury came over, and bright arsenical flowers arose in the neck of the retort. Dr Lewis observes, that the crackling noise of tin in bending may possibly arise from its arsenic; as those operations which are said to separate arsenic from the metal, likewise deprives it of this property.

1221
Dr Lewis's
observa-
tion.

Tin may be alloyed, in any proportion, with all metals by fusion: but it absolutely destroys their ductility,

and renders them brittle, as in bell-metal; whence this metal has obtained the name of *diabolus metallorum*.

Iron is dissolved by tin in a heat far less than that in which iron itself melts; the compound is white and brittle. Iron added to a mixture of lead and tin, takes up the tin, leaving the lead at the bottom; and, in like manner, if lead, tin, and silver, are melted together, the addition of iron will absorb all the tin, and the tin only. Hence an easy method of purifying silver from tin.

Tin, notwithstanding it is, like lead, soon deprived of its lustre by exposure to the air, is nevertheless much less liable to rust than either iron, copper, or lead; and hence is advantageously used for covering over the insides of other metalline vessels. The amalgam of mercury and tin is employed to cover one of the surfaces of looking-glasses; by which they are rendered capable of reflecting the rays of light. The amalgam also, mixed with sulphur and sal ammoniac, and set to sublime, yields a sparkling gold-coloured substance called *aurum mosaicum*; which is sometimes used as a pigment. This preparation is commonly made from quicksilver and tin, of each two parts, amalgamated together; and then thoroughly mixed with sulphur and sal ammoniac, of each one part and a half. The mercury and sulphur unite into a cinnabar, which sublimes along with the sal ammoniac; and, after sublimation, the *aurum mosaicum* remains at the bottom.
